

The University of Toronto
Chemical Library

Presented
to

The University of Toronto Library
by

William Lash Miller, B.A., Ph.D., C.B.E.

Professor Emeritus of Physical Chemistry
for

A Departmental Library to be under
the control of the Professor of

Chemistry according to the conditions
set out in a letter from the Librarian
of the University dated March 21st

1938.

Digitized by the Internet Archive

THE JOURNAL

OF THE

///
Society of Chemical Industry.

VOL. XXIV.—1905.

373655
11. 12. 39

LONDON:

VACHER & SONS,

GREAT SMITH STREET, WESTMINSTER, S.W.

The Society of Chemical Industry.

LIST OF PAPERS READ BEFORE SECTIONS OF THE SOCIETY DURING THE YEAR 1905.

N.B.—The words within () indicate the Journal in which the Paper appears and the Section and Page which it was read.

	PAGE		PAGE
Ardern, E. See Fowler, G. J.		Ferguson, W. C. Description of Method Employed in Preparing the Tables of Specific Gravity of Sulphuric Acid, Nitric Acid, Hydrochloric Acid and Ammonia, Adopted by the Manufacturing Chemists' Association of the United States. (31 July, New York)	781
Armstrong, H. E. The Mechanics of Fire. (15 May, London)	473	Floris, R. B. See McGowan, G.	
Atwater, C. G. Coke Oven Gas. (15 June, New York)	568	Ford, J. S., and Guthrie, J. M. On the identity of the Hydrolytic Products of Starches of Various Origins. (15 June, Scottish)	605
Bailey, G. H. Higher Education and Chemical Industry. (15 Dec., Manchester)	1205	Forrest, C. N. See Richardson, C.	
Ball, S. F. Commercial Fuel Oil. (16 Jan., New York)	18	Fowler, G. J., and Ardern, E. Suspended Matter in Sewage and Effluents. (15 May, Manchester)	483
Barnett, R. E. Magnalium and other Light Alloys (15 Aug., Yorkshire)	822	Frasch, H. A. A New Caustic Soda Process. (16 Jan., New York)	17
Baty, E. J. Methods of Temperature Indication. (15 April, Liverpool)	507	Gair, C. J. Dickenson. The Estimation of Naphthalene in Coal Gas. (30 Dec., London) ..	1279
Beadle, C., and Stephens, H. P. The Influence of Gelatin Sizing on the Strength of Paper. (31 July, London)	775	Gardner, W. M., and Lloyd, L. L. Notes on Water Softening. (29 April, Yorkshire)	392
Blakey, W. See North, B.		Garrett, F. C., and Lomax, E. L. Determination of Sulphur in Petroleum and Bituminous Minerals. (15 Dec., Newcastle)	1212
Brownison, H. W. The Proof of Percussion Caps. (29 April, London)	381	Gerard, T. A. The Composition of Scouring Soaps. (15 May, Nottingham)	488
Burford, S. F. Commercial Amyl Alcohol. (29 April, Nottingham)	391	Golding, J., and Feilmann, E. Taint in Milk Due to Contamination by Copper. (30 Dec., Nottingham)	1285
Carey, E. Address to Liverpool Section on "Chemical Industries of the United States." (16 Jan., Liverpool)	3	Griffin, M. L. Standard Methods of Sampling: A Review with Some Suggestions. (28 Feb., New York)	183
Firing with Coal Dust. (29 April, Liverpool) ..	369	Grossmann, J. An Improved Method of Indigo Testing. (15 April, Manchester)	308
Carpenter, R. Forbes, and Linder, S. E. Studies on the Claus K��n Reaction. Part III. (31 Jan., Liverpool)	63	The Recovery of Products of Commercial Value from Sewage Sludge. (30 June, Manchester)	655
Carulla, F. J. R. Tanks for Carrying Tar and Gas Liquor by Rail. (28 Feb., Nottingham) ..	185	Guthrie, J. M. See Ford, J. S.	
Case, Willard L. Generation of Producer, Mond and Blast-Furnace Gases. (15 June, New York) ..	592	Hackford, J. E. See Trotman, S. R.	
Caspari, W. A. Notes on Gutta Percha and Balata. (30 Dec., London)	1274	Hake, C. Napier. A Cause of Exudation of Nitroglycerin from "Gelatin Compounds." (15 Sept., Sydney)	915
Claffin, A. A. Quick Process Tanning of Sole Leather. (29 April, New York)	587	and Lewis, R. J. On the Formation of Sulphuric Esters in the Nitration of Cellulose, and their Influence on Stability. (29 April, London)	374
Cobb, J. W. Natural and Induced Draught. (31 May, Yorkshire)	528	and Lewis, R. The Formation of Sulphuric Esters in the Nitration of Cellulose and their Influence on Stability. (15 Sept., London)	914
Coleman, W. H. A Regulating Valve for Controlling the Admission of Steam to Vitriol Chambers. (15 May, Manchester)	482	Hanson, H. Norman. See Richardson, F. W.	
Davis, B., and Edwards, C. W. Chemical Combination of Oxygen and Hydrogen under Action of Radium Rays. (31 March, New York) ..	266	Harvey, T. F. Temperature Corrections for Use with the Abbe Refractometer, and Refractive Indices of some Fixed and Essential Oils. (15 July, Nottingham)	717
Denham, H. G. The Temperature of Combustion of Methane in the Presence of Palladiumised Asbestos. (15 Dec., London)	1202	and Wilkin, J. M. The Composition of Nux Vomica Fat. (15 July, Nottingham)	718
Divine, R. E. The Use of Tannic Acid in Determining Alumina. (16 Jan., New York) ..	11	Holmes, W. E. See Proctor, H. R.	
Dreaper, W. P. Theory of Dyeing. H. Pseudo-Solution and De-Solution. (15 March, London) ..	223	Howard, B. F., and Perry, F. Salts of the Alkaloid Cinchonamine. (30 Dec., London)	1281
Duckworth, H. S. Application of Electrolytic Chlorine to Textile Bleaching. (30 Nov., New England)	1157		
Dunn, J. T. See Pattinson, J.			
Edwards, C. W. See Davis, B.			
Feilmann, E. See Golding, J.			

	PAGE
Hart, S. Recent Advances in the Electro- tallurgy of Iron and Steel. (15 Jan., Manchester) 589	
Hart, S. See Richards, F. W.	
Kilb, F. S. See Schulzrowitz, P.	
Lane, N. J. Mineral Constituents of Soda Ash and its Adulterants. (28 Feb., Nottingham) 187	
Lane, N. J. Constants of Persimmon. (29 April, New York) 349	
See Wesson, D.	
Langmuir, A. C. The Determination of Residual Sulphur. (16 Jan., New York) 12	
Leach, J. W. The Determination of Sulphur in Iron. (29 April, London) 385	
Lester, J. H. Moisture Tests of Wood. Part II. (28 Feb., Manchester) 171	
Lewis, R. J. See Blake, C. Norman.	
Lewkowitsch, J. Evaporation of Solutions Containing Salts. (30 Nov., London) 1119	
Lieber, H. Improved Methods of Applying Radiation (15 March, New York) 230	
Linder, S. E. See Carpenter, R. T. Piles.	
Lloyd, L. L. See Gardner, W. M.	
Lomax, E. L. See Garrett, F. C.	
Longden, A. H. See Ward, G. J.	
Louis, H. The Dressing of Minerals. (15 Dec., Newcastle) 1208	
Lovibond, J. W. On the Fading of Inks and Pig- ments. (31 March, London) 262	
Lowe, W. F. Notes on the Accuracy of the Dry- Ash of Cellulose and Iron Crucibles. (16 June, New York) 6	
MacArthur, J. S. Gold Extraction by Cyanide: a Retrospect. (15 April, Scottish) 311	
McGowan, G., and Floris, R. B. Estimation of Acids in Fats: a Shortened Method. (14 March, London) 265	
Mann, E. A. Natural Gas in Western Australia. (30 Dec., London) 1283	
The Spirit Strength of Essences. (30 Dec., London) 1284	
Matthews, J. Merritt. The Effect of Alkaline Soor- ing Agents on the Strength of Woollen Yarns. (30 June, New York) 659	
Moore, Russell W. Analyses of Soda. (15 May, New York) 487	
Morgan, G. T., and Richards, F. E. Azo Colouring Matters Derived from <i>AR</i> Tetrahydro- <i>a</i> - Naphthylamine. (30 June, London) 652	
Motion, J. See Woollen, E. C.	
Muspratt, M. The Wood Distillation Industry. (29 April, Liverpool) 372, 473	
Nagel, O. Utilisation of Gas from Suction Pro- ducers. (15 June, New York) 597	
Neil, J. Miller. The Recovery of Tin Scrap. (15 Feb., Canadian) 121	
North, B., and Blakey, W. The Preparation of Standard Solutions of Sulphuric Acid. (29 April, Yorkshire) 395	
O'Sullivan, J. A. Method of Determining the Protolytic Activity of Peppine. (15 Aug., Nottingham) 830	
Otsuki, C. Action of Hydrogen Peroxide on a Photographic Plate in the Dark. (15 June, London) 575	
Influence of the Length of the Time of Develop- ment on the Degree of Darkening of the Photographic Plate. (15 June, London) 583	
Pattinson, H. Selwyn. Determination of Sulphur in Pyrites, by Langes' Method. (16 Jan., Newcastle) 7	
and Redpath, G. C. Methods for Separating and Determining Zinc in Blends and Other Natural and Artificial Products. (15 March, Newcastle) 228	
Pattinson, J., and Dunn, J. T. Some Sources of Error in Sulphur Determinations. (16 Jan., Newcastle) 10	
Pennock, J. D. The Mond Process. (15 June, New York) 599	
Perry, F. S. See Howard, B. E.	
Petrie, J. M. The Mineral Oil from the Torbanite of New South Wales. (16 Oct., Sydney) 996	
Procter, H. R., and Holmes, W. E. The Oxidation of Oils. (30 Dec., Yorkshire) 1287	
Priestman, H. The Microscopical Examination of Sumach Adulterants. (15 March, York- shire) 231	
Redpath, G. C. See Pattinson, H. Selwyn.	
Reid, W. F. Some Chemical Aspects of the St. Louis Exhibition. (31 Jan., London) 71	
Richards, F. E. See Morgan, G. T.	
Richardson, C., and Forrest, C. N. Carbon Tetra- chloride and its Use as a Solvent for Dif- ferentiating Bitumens. (15 April, New York) 310	
Richardson, F. W., and Hanson, H. Norman. The Valuation of Lubricants with Special Reference to Cylinder Oils. (15 April, Yorkshire) 315	
and Jaffie, A. Olive Oils and the Free Oleic Acid Question in Wool-combing. (31 May, Yorkshire) 534	
Schulzrowitz, P. Standards of Purity for Fermented and Distilled Liquors. (28 Feb., New York)	176
and Kaye, F. The Chemistry of Whisky. Part II. (15 June, London) 585	
Schwitzer, M. Tin in Alaska. (30 June, New York)	659
Seligman, R., and Willott, F. J. The Determination of Zinc in Light Zinc-Aluminium Alloys. (30 Dec., London) 1278	
Sundall, R. W. The Manufacture and Use of Art Papers. (31 July, London) 770	
Steed, T. The Temperature of Solutions Heated by Open Steam. (15 June, Sydney) 606	
Stevens, H. P. See Beadle, C.	
Tatlock, R. R., and Thomson, R. T. The Deter- mination of Small Proportions of Bromine and Chlorine in Iodine. (28 Feb., Scottish)	187
Thompson, G. W. The Determination of Acetic Acid in White Lead. (15 May, New York)	487
Thomson, R. T. See Tatlock, R. R.	
Toeh, M. New Paint Conditions Existing in the New York Subway. (31 May, New York)	527
Trotman, S. R. Damage Caused by Magnesia Soaps in Bleaching. (31 March, Nottingham) ..	267
and Hackford, J. E. Strychnine Tannate and its Use in the Analysis of Tanning Materials. (15 Nov., Nottingham) 1096	
Turner, T. The Physical and Chemical Properties of Slags. (30 Nov., Birmingham) 1142	
Ward, G. J., and Longden, A. H. Effect of Sulphur on Silicious Pig Iron. (28 Feb., Notting- ham) 189	
Wesson, D., and Lane, N. J. The Quantitative Analysis of Lard. (15 July, New York) ..	714
White, J. Standard Methods of Analysis. (29 April, Nottingham) 390	
Wilkie, J. M. See Harvey, T. F.	
Williams, W. S. Valuation of Tannic Acid from the Point of View of the Dyer and Calico Printer. (31 Aug., New York) 877	
Willott, F. J. See Seligman, R.	
Woods, J. Rayle. A New Indicator. (30 Dec., Manchester) 1284	
Worden, E. C., and Motion, J. Preparation of Volumetric Solutions. (28 Feb., New York)	178
Wright, A. M. Analyses of some New Zealand Coals. (15 Dec., Sydney) 1213	

Journal of the Society of Chemical Industry.

INDEX OF VOL. XXIV.—1905.

INDEX OF AUTHORS' NAMES.

N.B.—In this Index (P) indicates that the matter referred to is an abstract of a Patent.
The titles of new books are given within quotation marks.

A

	PAGE
Aarts, J. G. Coal; Process and Apparatus for Distilling and Carbonising — (P)	1008
See Water-Gas-Maatschappij, etc.	324, 325
Abel, E. "Hypochlorite und Elektrische Bleiche"	516
See Cowper-Coles	908
Abel, J. See Badische Anilin und Sodafabr.	669
and others. Sorel Cement; Manufacture of — (P)	590
Abelous, J. E. and others. Adrenalin; Colorimetric Determination of — by means of Iodine	693
Abendroth, H. A. Ammonia Still (P)	722
Abraham, H. Metallic Wires; Electrolytic Production of Fine —	679
Abraham, J. See Milwaukee Evaporator Co.	880
Abt, A. Chromaline D (Moriant)	615
Ach, F. See Boehringer und Soehne	249
Ach, L. See Boehringer und Soehne	1188
Acheson, E. G. See North American Trust Co.	499
Ackermann, E., and Steinmann, A. Alcohol in Beer: Determination of — by the Zeiss Immersion Refractometer	563
Actienges. für Anilinfabr. <i>p</i> -Aminobenzoic Acid; New Salts of the Ethyl Ester of — (P)	1189
<i>p</i> -Aminophenolsulphonic Acid; Preparation of — (P)	886
Aromatic Bases; <i>o</i> -Nitro Derivatives and <i>o</i> -Amino Derivatives — (P)	1207
1,8-Arylnaphthylaminesulphonic Acids; Manufacture of — (P)	669
Barbituric Acid Derivatives; Manufacture of — (P)	289, 345, 512
Bromocellin; Preparation of — (P)	512
Chromium Preparation for Sensitising Films (P)	1084
Colour Lakes from Azo Dyestuffs; Manufacture of — (P)	1243
Colour Lakes; Manufacture of — from Sulphur Dyestuffs (P)	203
Dialkyl Derivatives of Malonyl- <i>p</i> -phenetide (P)	1188
Diaminodiphenylamine Sulphonic Acid, and Process of Making same (P)	1105
3,4-Dichloraniline; New Sulphonic Acid of — (P) ..	1010
1,3-Dimethylxanthine and 1,3,7-Trimethylxanthine; Double Salt of — (P)	1254
Dyeing Furs, Hairs and Feathers (P)	331
Dyestuff; Monoazo —, and Process of Making same (P)	1222
Dyestuff; Sulphide, Yellow — (P)	541
Dyestuff; Sulphur — (Orange) (P)	271
Dyestuff; Yellow-Red Azo — (P)	1167
Dyestuffs; Cyanine —, for Photographic Purposes. (P) ..	346
Dyestuffs of the Cyanine Series; Preparation of Sensitising — for Photography (P)	560
Dyestuffs derived from 5-Nitro-2-aminophenol (P) ..	1298
Dyestuffs; New Sulphurised — (P)	1167
Dyestuffs, Sulphide; Production of — on the Fibre (P) ..	618
Dyestuffs, Sulphur; Manufacture of — and Materials for their Production (P)	795
Dyestuffs; Sulphurised — (P)	23

Actienges. für Anilinfabr.—cont.

Dyestuffs; Yellow Sulphide — (P)	1105
Flash Lights for Photography (P)	44
Glycolic Acids of Pyrogallol and its Alkyl Ethers; Preparation of — (P)	559
Indophenols; Manufacture of — (P)	24, 1239
Indophenols; Preparation of Acetylated — (P) ...	1062
Lakes from Azo Dyestuffs (P)	1189
Lakes; Orange or Yellowish-Red — from Azo Dyestuffs (P)	1117
Lakes; Red — from Azo Dyestuffs (P)	1117
Leather; Dyeing of — (P)	842
Naphthazine Derivatives; Preparation of — (P) ..	615
Naphthylamine Sulphonic Acids; Arylated 1,6- or 1,7- — (P)	434
5-Nitro-2-aminophenol; Manufacture of — (P) ...	1298
Nitro-derivatives of Aromatic Bases; Manufacture of — (P)	193
Peptone; Manufacture of — from Silk Fibroin (P) ..	1249
Pepsin; Conversion of — into a Stable, Water-Soluble Product (P)	1249
<i>p</i> -Phenetidine; New Derivative of — (P)	1125
1,6- and 1,7-Phenyl- or Tolylnaphthylaminesulphonic Acids; Prep. of — (P)	796
1,8-Phenyl- or Tolylnaphthylaminesulphonic Acid; Preparation of — (P)	796
Photographic Development; Process of — (P) ...	1084
Powdered Substances; Facilitating the Moistening — (P)	1162
Pyroxylin, Collodion-Cotton, &c.; Manufacture of Sheets, &c., of — (P)	248
Salicylic Acid; Making the Phenyl or Naphthyl Ethers of — (P)	346
Theobromine; Soluble Compounds of — (P)	1188
Actienges. für Chem. Ind., Vienna. Nutritive Substance from Blood (P)	101
Actienges. für Chem. Ind. Ores; Preparation of — for Smelting (P)	624
Adam, P. Petroleum Spirit; Vaseline Oil; Vaseline	325
Adams, A. J. See International Wood Distilling Co.	722
Adams, M. J. Filter Beds for Sewage (P)	452, 982
Adams, S. B. Gum; Apparatus for Straining — (P) ..	1315
Adams, W. W. jun. See American Patent Kid Co.	627
Adamson, R. H. Cotton and Linen Yarns and Cloths; Scouring — (P)	330
Wool and Woollen Goods; Scouring and Milling — (P)	330
Addicks, L. Copper; Effect of Impurities on Electrical Conductivity of —	740
Adlam, E. G. Beer; Apparatus for Chilling and Carbonating — (P)	1248
Adler, R. and O. Carbohydrates; Reactions of —	351
Administration der Minen von Buchsweiler. Sodium Ferrocyanide; Manufacture of — (P)	28
Adriaanse, J. Ammoniacal Liquors from Manufacture of Gas; Apparatus for Distillation of — (P)	1220
Advertising Mirrors Co., The. See King, A. W.	804
Ageron, J. A. Oxygen; Apparatus for Production of — (P)	969

PAGE

	PAGE
Arundel, A. S. D. Inks and Pigments; Discussion on the Fading of —	261
Aschan, O. "Chemie der Alcyklischen Verbindungen"	1261
Ash, H. W. See Warren Brothers Co.	127
Ashby, C. J. Retorts; Inclined —, for Gas Making (P)	129
Ashcroft, E. A. Electrolytic Cells; Apparatus for Agitating Contents of — (P)	625
Metals of the Alkali Group; Production of — by Electrolysis (P)	1116
Asher, T. Sponges; Dyeing of — (P)	1228
Ashley, H. E. Glass; Iridescent Stains on —	1014
Pottery Bodies high in Silica; Crazeing of — by Over-firing	1015
Silica Determinations	49
Ashley, R. H. Sulphites; Oxidation of — by Iodine in Alkaline Solution	561
Askenasy, P., and Mugdan, M. Acetylene Tetrachloride; Production of — (P)	150
and Mugdan, M. Hydrochloric and Sulphuric Acids; Making and Separating — (P)	1230
Askham, W. H. See Heymann	1053, 1063
Aso, K. Oxidases; Investigation of the —	691
Aspinall, F. B., and Cannon, M. J. Wort; Treatment of — (P)	451
Assmann, O. Gas under Pressure for Motive Purposes (P)	1101
Astre, C., and Ville, J. Antipyrine; Compound of Mercuric Oxide with —	856
Astruc, A. Piperazine; Glycerophosphates of —	344
and Péguier, G. Pyramidone; Determination of —	1259
Atkins, G. J. Electrodes for Electrolytic Apparatus (P)	416
Poles or Electrodes of Electrolytic Apparatus (P)	446
Atteaux, F. E. Textile Bleaching by Electrolytic Chlorine; Discussion on —	1160
Attix, J. C. Fine Ore, Flue-Dust, &c.; Utilisation of — in the Blast-Furnace	278
Atwater, C. G. Coke-Oven Gas	598
Mond Producer; Discussion on the —	604
Aubel, E. van. Iodoform; Decomposition of — by the Combined Action of Light and Oxygen	103
Aubert, J. See Baron	1181
Aubertin, L. F. J. L. Papers; Baths used for Manufacture of Coated — (P)	984
Anbry, H. Furnaces; Electric — (P)	1313
Anbry, P. Dyeing Machine for Yarns (P)	86
Auchinachie, P. Vanadium; Obtainment of Metallic — (P)	1179
Audiau, M. Metallic Cables; Rendering — Non-oxidisable (P)	1178
Auerbach, F., and Barschall, H. Formaldehyde; Studies on —	1187
Aufsberg, C. Food Products containing Iron; Preparing — (P)	207
Augier, A. Carbon Bisulphide; Process of Obtaining — (P)	1021
Auld, S. J. M. See Henry	1246
Aurenque, J. B. A. Gases or Vapours; Recovery of — by Refrigeration (P)	747
Austin, H., and others. Condensing and Cooling Apparatus (P)	234
Autenrieth, W., and Bernheim, R. <i>p</i> -Phenetidine; Ethyl-sulphonie Derivatives of —	40
Axelrod, S. Rubber; Solubility in Benzene of Different Kinds of —	1180
Aylsworth, J. W. See Edison Storage Battery Co.	244

B

Baborovsky, G. Magnesium Anodes; Behaviour of —	894
Bach, A. Catalase; Study of —	694
Bach, J. Furnaces; Manufacture of Refractory — (P)	1054
Bachrach, D. Nitrocellulose or Similar Substances; Making Compounds of — (P)	901
Bacovescu, A., and Pietet, A. Isostrychnine; Characteristics of —	1123
Bacqua, J. See Mars	1166
Badger, J. Liquid Fuel; Burning of — (P)	189
Badische Anilin und Soda Fabr. Acid Nitriles; Manufacture of — (P)	84
Aldehyde Derivatives and their Application (P)	1227, 967, 1300
Alizarine; Manufacture of — (P)	128
Alkaline Metal Oxide; Manufacture of — (P)	969
Alkalis; Manufacture of Dehydrated Caustic — (P)	731
Anthracene Derivatives; Production of — (P)	1223
Anthranilic Acid and Formaldehyde; Condensation Product from — (P)	615
Anthraquinone Derivatives (P)	1298
Arsenic; Removal of — from Gases (P)	969
Azo Dye Lake, and Manufacture of same (P)	1075
Cellulose; Acetylation of — (P)	454

Badische Anilin und Soda Fabr.— <i>cont.</i>	PAGE
Chloro- and Bromophthalimide; Preparation of — (P)	1298
Cyanides; Purification of — (P)	333
Dichlorodimethylfluorane (Pyrene Dyesuff), and Manufacture of same (P)	328
Discharges on Dyed Materials; Production of Coloured — (P)	616
Discharges on Fabrics Dyed with Halogenated Indigo (P)	438
Discharges; Production of — by means of Hydrosulphites (P)	672
Discharging Compound (P)	841
Discharging by means of Hydrosulphites (P)	130
Discharging Pastes for Discharge of Dyed Textile Fabrics (P)	966
Dye Compound (P)	84
Dyestuff; Anthracene — (P)	849, 841
Dyestuff of the Anthracene Series (P)	1298
Dyestuff; Anthracene — and Manufacture thereof (P)	541
Dyestuff; Anthracene Violet — (P)	434
Dyestuff; Anthraquinone — (P)	128
Dyestuff; Azo — adapted to form Lakes (P)	726
Dyestuff; Azo — insoluble in Water (P)	726
Dyestuff; Azo — and Intermediate Products, suitable for Production of Lakes (P)	83
Dyestuff; Azo — and Lakes therefrom; Manufacture of — (P)	128, 128
Dyestuff; Blue Sulphur — (P)	669
Dyestuff; Mono-azo —, for Manufacture of Lakes (P)	191
Dyestuff; Monoazo, Red; Production of — (P)	329
Dyestuff; Red Monoazo — for Production of Lakes (P)	433, 726, 964
Dyestuff; Sulphur (Violet) (P)	128
Dyestuff; Yellow Cotton Sulphide; Preparation of a — (P)	797
Dyestuffs; Anthracene — (P)	542, 919, 919
Dyestuffs; Anthracene, Grey — (P)	433
Dyestuffs of the Anthracene Series (P)	841, 964
Dyestuffs; Azo — (P)	541, 810
Dyestuffs; Azo — and Intermediate Products (P)	433, 963
Dyestuffs and Derivatives from Anthracene (P)	1010
Dyestuffs; Hydroxyazo — (P)	83
Dyestuffs; α -Hydroxyazo — (P)	1224
Dyestuffs; Indigo; Preparing Compounds of — (P)	615
Dyestuffs; Manufacture of a New Series of Anthracene (P)	726
Dyestuffs; Monoazo Blue — (P)	542
Dyestuffs; Mono-azo (Orange) — (P)	84
Dyestuffs; Monoazo — for Preparation of Lakes (P)	434, 434
Dyestuffs; Monoazo (Red) — (P)	84
Dyestuffs; Monoazo — susceptible to Chroming (P)	434
Dyestuffs; Monoazo Yellowish Red — (P)	542
Dyestuffs of the Naphthalene Series; Manufacture of (P)	23, 725
Dyestuffs; Pyrene — (P)	493
Dyestuffs; Sulphide — for Cotton (P)	24
Dyestuffs; Yellow to Orange-Yellow, suitable for Preparing Lakes (P)	1224
Electric Arcs; and Apparatus for Production of Reactions in Gases by means of — (P)	1178
Formaldehyde-Sulphoxylate and Manufacture of same (P)	841
Gases; Producing Reactions in — by means of Electricity, and Apparatus therefor (P)	201
Hydrosulphites; Producing Discharges by means of — (P)	87
Hydrosulphites; Production of Dry and Stable — (P)	132, 333, 673, 1172
Hydroxyalkylaniline; Manufacture of — (P)	84
Hydroxyethylaniline and its Derivatives; Manufacture of — (P)	541
Indigo and its Homologues, &c.; Reduction of — (P)	1223
Indigo; Manufacture of — (P)	84
Indigo Paste for Direct Use in the Fermentation Vat (P)	24
Indigo; Printing with — on Vegetable Fibre (P)	543
Indigo; Production of — (P)	885
Indigo; Purification of — (P)	193
Indigo, &c.; Reduction of — (P)	495
Indigo; Stable Chloro-derivatives of — (P)	1224
Indigo Vat; Hydrosulphite — (P)	841
Indigo White; Halogenated — (P)	1298
Indigo White; Manufacture of — (P)	127
Indolic Bodies; Manufacture of — (P)	964
Indoxyl; Acylated — and Manufacture thereof (P)	84
Indoxyl and its Derivatives; Production of — (P)	127, 541
Lakes; Manufacture of — (P)	448, 448
Manufacture of Colouring Matter — (P)	506
Monoalkylaminohydroxybenzylbenzoic Acid; Preparation of — (P)	1298
Oxidising Methyl Groups in Aromatic Hydrocarbons (P)	151
Phenyglycine Salts; Manufacture of — (P)	541
Platinum Contact Substances; Revivification of — (P)	240
Reducing Agents; Manufacture and Application of — (P)	727
Rhodamines; Manufacture of — (P)	329
ω -Sulphomethylanthranilic Acid; Preparation of — (P)	542
ω -Sulphomethyl Derivatives of Aromatic Amines; Preparation of — (P)	797
Sulphuric Acid; Catalytic Substance for Manufacture of — (P)	845
Sulphuric Acid; Manufacture of — (P)	1066
Wool; Production of Blue to Blue-Black Shades on — (P)	273

	PAGE		PAGE
Bay, I. Diphenylamine; Reaction of — with Nitric Acid	458	Bégin, J. J. M. Gas-Purifying Materials; Treatment of — and Apparatus therefor (P)	1293
Bayer, F. and Co. Aldehydes; Preparation of — (P) ..	630	Sulphur and Cyanides; Process and Apparatus for Extraction of — from Spent Oxide, &c. (P)	1067
Alkyl Ethers of Aromatic <i>o</i> -Tolyl Alcohol; Preparation of — (P)	560	Beck, H. See Fremy	83
2-Alkylxy-pyrimidines; Preparation of — (P)	456	Becker, T. See Bayer, F. and Co.	686
Anthraquinone Derivatives (P)	963	Becker, See Seibt, and Becker	671
Anthraquinone Derivatives containing Nitrogen (P) ..	1165	Beckmann, C. Calcium; Some Applications of — (P) ..	354
Anthraquinone and its Derivatives; Introduction of Hydroxyl Groups into — (P)	541	Beckwith, C. P. See Alcock	103
Anthraquinone Derivatives; Manufacture of — (P) ..	271, 725, 1000	Bequerel, P. Seeds; Effect of Liquid Air on Germination of —	519
Anthraquinone and its Derivatives; Preparing Aryl Ethers of — (P)	885	Bedford, J. Armour Plates; Manufacture and Treatment of Compound — (P)	970
Anthraquinone Derivatives; Production of — (P) ..	127	Bedford, J. E. Oxidation of Oils; Discussion on — ..	1200
Dialkylbarbituric Acid; Manufacture of — (P) 559, 680, 749, 813		Bedford, J. E. and C. S., and Crowther, B. Soap; Process and Apparatus for Preparation of — (P)	1170
C.C.-Dialkylbarbituric Acids; Preparation of — (P) ..	1189	Beeman, J. S. Semi-Liquid or Viscous Materials; Process and Apparatus for Mixing, Churning, &c. (P)	537
Diiminothiopyrimidine and its C.C.-Dialkyl Substitution Products; Preparation of — (P)	814	Beemer, M. W. Liquids; Dashers or Beaters for Mixing or Agitating — (P)	663
Dye; Sensitising — for Photographic Purposes (P) ..	210	Beers, L. E. Distilling Apparatus (P)	959
Dyestuff, Alizarin — (P)	669	Behaghel, W. See Badische Anilin und Soda Fabrik ..	84
Dyestuff, Anthracene — (P)	541	Béhal, A. Celluloid; Manufacture of — (P)	855
Dyestuff, Anthracene, Blue — (P)	726	and Sommelet, M. Aldehydes $R_2CH \cdot CHO$ and $RR'CH \cdot CHO$; Preparation of — (P)	750
Dyestuff, Anthraquinone — (P)	1167	and Sommelet, M. Aldehydes $R_2CH \cdot CHO$ and $RR'CH \cdot CHO$; Preparing the — (P)	345
Dyestuff, Anthraquinone, Green — (P)	433	and others. Camphor; Synthetic Preparation of — (P)	867, 985
Dyestuff, Anthraquinone, Green-blue — (P)	433	Behrens, E. A. and J. G. Carbonic Acid; Process and Apparatus for Making — (P)	845
Dyestuff, Anthraquinone, Greenish-blue (P)	433	Behrens, G. E., and Taylor, G. Wool-Wash Waters; Apparatus for Treating — (P)	141
Dyestuff, Azo — (P)	840	Behrens, H. Metals of the Yttrium and Cerium Groups; Action of some Organic Acids on —	548
Dyestuff, Azo —, suitable for Manufacture of Lakes (P)	1061	Behrens, R. See Farbenfabriken of Elberfeld Co.	210
Dyestuff, Reddish Azo — (P)	796	Bejericzek, W., and Gosling, N. Sarcina; An Obligatory Anaerobic Fermentation	1317
Dyestuffs, Anthracene; Manufacture of — (P)	193	Beiby, G. T., and H. N. Metals; Influence of Phase Changes on the Tenacity of Ductile —	1237
Dyestuffs of the Anthracene Series (P)	128, 1223	Bell, G. W. Gunotton Blocks; Method and Apparatus for Formation of — (P)	690
Dyestuffs of the Anthracene Series, and Intermediate Products (P)	1061	Bell, J. Carter. Moisture Tests of Wood Pulp; Discussion on —	175
Dyestuffs of the Anthraquinone Series, and Intermediate Products for their Manufacture (P)	1223	Sewage Sludge; Discussion on Recovery of Products from —	657
Dyestuffs; Azo — from Aminoanthraquinone-Sulphonie Acids (P)	1223	Suspended Matter in Sewage and Effluents; Discussion on —	487
Dyestuffs; Azo — and Intermediate Products (P) ..	963	Bell, M. K. Dye Compound; A New — (P)	83
Dyestuffs, Azo; Manufacture of — (P) 1009, 1222, 1222		Bellars, A. E. See Morrell	515
Dyestuffs, Azo; Preparation of New — (P)	329	Bellenoux, E. S. Calcium Nitrate in Agriculture	628
Dyestuffs; Green — of the Anthracene Series (P) ..	1010	Bellier, J. Walnut Oil; Detection of Foreign Oils in — ..	459
Dyestuffs, Monoazo; Production of — (P)	1222	Bellon, F. G. Lead-Potassium Sulphate; Existence of a Definite —	561
Erythrohydroxyanthraquinone, Anthranilin, and Chrysazin; Manufacture of — (P)	841	Beltzer, F. J. G. Mercerising Industry; Studies on the — ..	965
Ethers of New Amino-alcohols (P)	1189	Bender, C. Match Igniting Compositions; Analysis of — Sulphur (in Co.)	1257
Flash Light; New — (P)	1031	Eschka's Method	293
Hydroxyanthraquinone Methyl Ethers; Preparation of — (P)	669	Bender, O., and Hediger, F. Smokeless Combustion in Hearths or Furnaces; Production of — (P) ..	838
Lake Fast to Light; Preparation of — (P)	552	Benedicks, C. Troostite; Nature of —	1069
Lakes from Azo Dyestuffs; Manufacture of — (P) ..	244, 448, 506, 566	Benjamin, G. H. Furnace; Electrical Metallurgical — (P) ..	1022
Lakes; Preparation of — (P)	742	Furnace; Metallurgical — (P)	897
<i>o</i> -Monobromo- <i>a</i> -aminoanthraquinones; Preparation of — (P)	886	Benker, F., and Hartmann, E. Copper; Extraction of — in form of Copper Sulphate (P)	1231
<i>a</i> -Nitroanthraquinones and their Derivatives; Replacing the Nitro Groups of — by Hydroxyl Groups (P)	796	Bennett, C. T. Eucalyptus Oil; Adulterated —	103
Pharmaceutical Compound; Manufacture of a New — (Salicylic Acid Monoglycol Ester) (P)	1030	See Umney	208
Pharmaceutical Compound (<i>m</i> -Tolylsemicarbazide); Manufacture of a — (P) .. 345, 455, 813, 985		Bennett, J. F., and Mastin, J. Pigments; Manufacture of — (P)	978, 1243
Phenol Compounds; Manufacture of New — (P) ..	345	Bennie, P. M. See FitzGerald	738
Photographic Emulsions; Colour Sensitive — (P) ..	456	Benemann, R. Nitro; Analysis of —	691
Photography; Pigment Process of — (P)	635	Benson, W. A. S. Jacketted Vessels (P)	663
Pyrimidine Derivatives; Manufacture of — (P) 512, 635		Bentrop, W. Gas; Increasing the Yield of Illuminating — by Introducing Water-Gas into Retorts (P) ..	612
Quinizarin; Manufacture of — (P)	796	Berdel, E. Colours for Pottery; Lead Non-Poisonous Fusible —	497
Silk; Artificial (P)	1209	Berg, W. N., and Sherman, H. C. Ammonia in Milk; Determination of —	293
Thiazol Sulphonic Acids; Production of — (P) 1061, 1168		Bergdolt, Malt; Determination of Yield of Extract in — ..	1038
Thiopyrimidine Derivatives; Preparation of — (P) ..	456	Bergendal, F. J. Furnaces for Calcining and Burning Briquettes of Ore, &c. (P)	958
<i>m</i> -Tolylsemicarbazide. See Pharmaceutical Compound, above.		Bergerhoff, E. Paper Half-Stuff; Manufacture of — (P) ..	1028
Triacetyl Cellulose (P)	686	Bergier, L. Silk; Artificial (P)	617
Bayerische Act. Ges. für Chem., &c., Fabr. See Hilbert ..	628	Bergmann, E. See Busch	271
Bayles, H. B. Fuel; Smokeless — (P)	836	Bergo, J. F., and Kainscop, D. Beer; Manufacture of Sterilised — (P)	1243
Bayliss, T. A. See King's Norton Metal Co.	1084	Berl, E. Sulphur Trioxide; Arsenic Pentoxide as Catalyst in the Formation of —	233, 1191

INDEX OF SUBJECTS.

N.B.—In this index, (P) indicates that the subject is a patent; (T.R.) indicates that the matter is in the Trade Report.

A		PAGE
Atm. Refractometer; Temperature Corrections for — with the — (Harvey)	717	
Abies alba Cones; Oil of — (Sassol)		
Acacatechin. See Dyestuffs.		
Acetaldehyde; Thermal Decomposition of — (Lange and Smith)	792	
Acetic Acid; Exemption from Duty for — in the Netherlands (T.R.)	355	
Production of — during Alcoholic Fermentation (Reisch)	11-3	
In White Lead; Determination of — (Thompson)	487	
Acetic Acids; Condensation Products (Perfumes) from Negatively Substituted — (P. Kroeveveld)	689	
Acetic Anhydride; U.S. Customs Decision on — (T.R.)	1044	
Acetone; Action of Magnesium Amalgam on — (Cour- turer and Meunier)	344	
Determination of — by the Iodoform Method (Keppeler)	460	
Manufacture of — in India (T.R.)	518	
Production of Iodoform from — by Electrolysis (Roush)	1253	
Pseudo-cyclohexadiene — and Making same. (P) Meister, Lucius and Bruning From Merling....	290	
Solutions; Reactions of Salts in — (Naumann)	26	
Source of Error in Determination of — by the Iodo- form Method (Vaubel and Scheuer)	252	
Acetyl Groups; Determination of — (Perkin)	293	
(Sudler, Hugh and Thomas)	563	
Acetylcel — Preparation of — (Hofmann)	748	
Acetylen. Reaction of — on Mercuric Chloride Solutions. Reaction — in Autogenous Solution (Traubel)	48	
Chlorination of — (P. Salzbergwerk, Neu Stass- furt)	1255	
Combustion of — (Bone and Andrew)	1005	
Dissolved — (Kuchel and Bournoville)	1101	
Purification of — by Means of Bleaching-Powder. (P. Fritz)	1294	
Treatment of — for Transportation and Storage. (P. Le Sueur)	191	
Acetylene Tetrachloride and Toluene; Reaction between — (Lavaux)	884	
Tetrachloride; Production of — (P. Askenazy and Mugdan)	150	
Tetrachloride; Production of Symmetrical — (P) Tomkins	902	
Acetylmethylcarbinol in Vinegars; Presence and Deter- mination of — (Pastureau)	745	
Acetylsalicylic Acid; U.S. Customs Decision on — (T.R.)	217	
Acetylsalicyphenetidine; Manufacture of — (P) Summers	150	
Acheson Process of Toughening Clays; Investigation of — (Minton)	133	
Acid Elevators. (P. Ceaglio)	881	
Acids; Apparatus for Recovery of Volatile — from Solu- tions. (P. Hewitt)	277	
Combined with Aluminium; Determination of — (Schmatolla)	349	
Detection of Formation of Complexes in Mixtures of — by Aid of Isohydric Solutions. (Hofmann)	295	
Earthenware Cocks for Use with — (P) Ruppel	123	
Electrolytic Reduction of Aromatic Carboxylic — to the Corresponding Alcohols. (Mettler)	634	
Fatty — See Fatty Acids.		
Influence of Various Sodium Salts on Solubility of Sparingly Soluble — (Phillip)	818	
Means for Elevating — (P) Lowndes From Hughes	124	
Organic; Electrolysis of — (Brochet and Petit)	280	
Pseudo —, and Pseudo-Bases. (Brühl and Schroeder)	296	
Acid-Proof Material. (P) Margat	136	
Acidimetry; Sodium Carbonate and Sodium Oxalate as Standard Substances in — (Sørensen and Andersen)	513	
Aconite Alkaloids; Research on the — XVI, XVII. (Dunstan and Andrews)	1252	
XVIII. (Dunstan and Henry)	1252	
XIX. (Dunstan and Henry)	1252	
Aconitine; New Reaction for — (Alvarez)	562	
Reagent for Detection of — (Alvarez)	752	
Address to Liverpool Section. (Carey)	3	
Presidential —	707	
Adhesive (Casein) and Manufacture of same. (P) Thubé and Prädubert	628	
Preparation of an — (P) Hey	507	
Adhesives; Production of — (P) Casein Co. of America From Brooks	144	
Adrenalin; Colorimetric Determination of — by Means of Iodine (Abelous and others)	693	
Physiological Activity of Substances Related to — (Dakin)	1124	
Synthesis of Substances Allied to — (Dakin)	686	
Aethusa Cynapium; Chemical Examination of — (Power and Tutin)	938	
Africa, Cape Colony; Castor Oil Production of — (T.R.)	1195	
Cape Colony; Oil and Paint Imports of — (T.R.)	1043	
East; Musa Fibres from —	1299	
East; Rubber from the Sotik Forest	978	
Portuguese East; Chemical Imports of — (T.R.)	946	
Rhodesia; Rubber from North-Eastern —	743	
Rhodesia; "Dande" Rubber from —	743	
South; Trade of Cape Colony. (T.R.)	989	
South; Trade of Natal. (T.R.)	990	
Agar-Agar; Limpid Solutions of — and Product of same. (P. Riebensahn)	338	
Agglomerant for Manufacture of Briquettes. (P) Marton	270	
Agglutinant for Manufacture of Fuel Briquettes, &c. (P) Ellis	191	
Agitating Apparatus:— (P) Ashcroft	625	
(P) Bevereux	242	
(P) Ehrhardt	1316	
for Use in Electro-Deposition of Metals. (P) Wood and Oaksford	1116	
Air; Apparatus for Carbureting:— (P) Bouchaud-Praceiq	836	
(P) Chazal	1219	
(P) Steel and Thoroton	665	
Apparatus for Liquefaction of — (P) Soc. l'Air Liquide (Procédé Claude)	969	
Apparatus for Ozonising — (P) Ozonair, Lim., and Joseph	1115	
Apparatus for Purification of —: (P) Harris	281	
(P) Barnabé, From Mugna	1006	
Apparatus for Regenerating Breathed out — (P) Bainberger, Böck and Wanz	1027	
Apparatus for Removing Moisture from — (P) Hesketh and Brier	1238	
Apparatus for Testing — (P) Milne and O'Connor	904	
Appliances for Extracting Moisture from — (P) Gayley	138	
for Blast-Furnaces; Drying of — (P) Soc. Grimault, Le Soufaché, et Felix	677, 975	
Carburetted; Apparatus for Production of —: (P) Godefroy	22	
(P) Philippe	884	
Carburetted Production of — (P) Shicks	1006	
Carburetted Production of — and Apparatus therefor:— (P) Caracristi	1057	
(P) Gore	1006	
Currents; Drying Materials by — (P) Lake. From Trump	77	
Device for Protecting — against Electric Discharges. (P) Electrical Purifying Co. From Werner	95	
Dust-Laden; Method and Apparatus for Purifying — (P) Barthelme	1055	
Extracting Moisture from — (P) Gayley	880	
Fan for Electrification of — (P) de Mare	550	
and Gas; Process and Apparatus for Preparing Mixtures of — (P) Selas Ges.m.b.H.	612	
and Gas; Process and Apparatus for Recovering Volatile Liquid from — (P) Hesketh	1161	
and Gaseous Mixtures; Separating — into their Elements. (P) Soc. l'Air Liquide et Levy	442	
Heating of — (P) Pauling	28	
Liquid; Separation of Oxygen and Nitrogen from — (P) Société des Procédés G. Claude	496	
and Nitric Oxide; Reaction between — (Lunge and Berl)	88	

Air—cont.	PAGE
Purifying — and Apparatus therefor. (P) Swan.	101
Regeneration of — and Apparatus therefor. (P) Bamberger, Böck and Wanz.	301
Air-Blast ; Process and Apparatus for Heating the — by Heat of the Slag. (P) von Ischewsky.	621
Alaska ; Tin in —. (Schwitzer).	659
Albans from Mikindani Rubber, from German E. Africa. (Tschirch and Müller).	607
from Sumatra Gutta-Percha. (Tschirch and Müller).	627
Albumin Compounds ; Hydrolysis of —. (Skraup).	333
Preparation of Pure — from Dilution Juices. (P) de Lewicki.	811
Preparation of Vegetable —. (P) Mitchell.	811
Preparations; Production of Blood —. (P) Langer.	1027
Solutions; Preparation of —. (P) Hoffschmidt.	510
Albuminoids ; Behaviour of — during Alcoholic Fermentation. (Iwanoff).	100
Oxidation of — by Calcium Permanganate. (Kutscher and Schenk).	252
Albuminous Substance from Maize. (P) Donard and Labbé.	853
Alcohol, Amyl ; Examination of Commercial —. (Burford).	391
Amyl; Formation of — in Fermentations by Beer Yeasts. (Elfront).	1247
Amyl; Impure Commercial —. (Richmond and Goodson).	314
Amyl; Manufacture of —. (P) Mishin and Lewin.	1121
Amyl; Preparation of Inactive —. (Freundler and Diamond).	1322
Apparatus for Distilling —. (P) Perrier.	287
in Aqueous Solutions; Determination of —. (Gaunt).	295
Aromatic; Preparation of the Alkyl Ethers of an —. (P) Bayer und Co.	560
In Beer; Determination of — by the Zeiss Refractometer. (Ackermann and Steinmann).	563
Carbureting — for Use as an Illuminant. (P) Villegoureux.	492
Cinnamyl (Styrone); Conversion of Cinnamic Aldehyde into —. (Barbier and Leser).	856
Denaturing of —:	
(Duchemin).	287
(P) Heidlberg.	101
(P) Phillips.	429
Denaturing of —. Report to French Finance Minister. (Lindet).	146
Ethyl; Acidity of Commercial — and its Variations during Storage. (Duchemin and Dourlen).	684
Ethyl; Preparation of Pure —. (Winkler).	1253
Ethyl; Spontaneous Oxidation of —. (Mathien).	900
Export of — from the German Customs Area in 1904. (T.R.).	254
in France during 1904. (T.R.).	299
Halogen Tertiary Bntyl ; Manufacture of —. (P) Aldrich and Beckwith.	103
Industrial Product Derived from —. (P) Sallé.	1102
for Industrial Purposes in Belgium. (T.R.).	299
for Industrial Purposes in the United States. (T.R.).	568
Industry of Italy. (T.R.).	53
Manufacture of — for Illuminating. (P) Plehu.	80
Manufacture of — from Wood Wastes. (P) Holanbek.	1079
Methods of Denaturing — Employed in Different Countries. (Lecomte).	1218
Methyl; Detection of — in Liquids containing Ethyl Alcohol. (Sadtler).	1128
Methyl; Detection of — in Spirit Preparations. (Fendler and Mannich).	1128
Methyl; Determination of — in Formaldehyde. (Gnehm and Kauffer).	213
Methyl; Taxation of — in France. (T.R.).	254
New Terpene — in Myrtle Oil. (von Soden and Elze).	1082
Peruvian New Law on —. (T.R.).	113
Plates for Apparatus for Concentrating and Rectifying —. (P) Calmant.	1183
Production of — during Fermentation. (Lindet and Marsais).	145
Recovery of Vapours of —. (P) Soc. Jean et Cie. et G. Raverat.	750
Rectifying Apparatus; Accumulator and Regulator for —. (P) Guillaume.	101
Report of Departmental Committee on Industrial — from Sawdust. (T.R.).	1329
Tax; French Customs Decision on the —. (T.R.).	254
Tax; U.S. Treasury Decision on French —. (T.R.).	1044
Tax; U.S. Customs Decision on French —. (T.R.).	520
Tax; U.S. Customs Decision on Perfumery —. (T.R.).	698
Taxation and Consumption of — in Italy. (T.R.).	359
Treatment of — for Heating, Lighting and Motive Power. (P) Rosalt.	191
Trust in Spain. (T.R.).	359
Wood-; Apparatus for —. (P) Rosencrans.	839
Alcohols, Amino ; Ethers of New —. (P) Bayer und Co.	1189
Amino; Preparation of —. (P) Meister, Lucius und Brüning.	560
Amino-; Preparation of — and their Derivatives. (P) Poulenc Frères and Fournéau.	43
Aromatic; Electrolytic Manufacture of — and their Derivatives. (P) Mettler.	559, 1188
and their Derivatives; Production of —. (P) Bouveault and Blanc.	151

Alcohols—cont.	PAGE
Ethyl and Methyl; Detection and Determination of — in Mixture. Leach and Lythgoe.	943
Monatomic and Polyatomic; Synthesis of —. (P) Grignard.	559
Phenolic; New Condensation Products of —. (P) Fabr. de L. Chim. Organique de L. 1244	1244
Polyhydric; Influence of Lead and Bismuth Salts on the Rotatory Powers of —. H. (Görmann).	1119
Primary; Preparation of —. (P) Bollmann and Blanc.	151
Reaction of Metal Ammoniums on —. (Chadway).	634
Solidified —. (P) Denayrouze.	129
Alcoholic Compound ; U.S. Customs Decision on —. (T.R.).	1195
Fermentation. See under Fermentation.	
Preparations; Detection of Wood Spirit in —. (Peters).	1192
Aldehyde ; U.S. Customs Decision on —. (T.R.).	255
Derivatives; Production of — and their Application as Discharging Agents. (P) Badische Anilin und Soda Fabr.	727
Aldehydes, Aliphatic ; (Condensation Products (Perfumes) from —. (P) Knoevenagel.	689
Dihydroxy-; Preparation of Aromatic —. (P) Sommer.	456
Electrolytic Oxidation of Aliphatic —. (P) New.	280
in Essential Oils; Neutral Sulphite Method for Determining —. (Sadtler).	1193
and Intermediate Products; Manufacture of —. (P) Darzens.	4
and Ketones; Condensation Products of — with Negatively Substituted Methyl or Methylene Compounds. (P) Knoevenagel.	1323
in Lemon Oil; Determination of —. (Berte).	563
New Reaction of — and Isomerism of their Oximes. (Conduché).	251
Preparation of —. (P) Bayer und Co.	690
R ₂ CH.CHO and R'R''CH.CHO; Preparation of —. (P) Behal and Sommelet.	345, 750
Synthesis of — by means of Formic Acid. (Houben).	718
Synthetic Preparation of —. (Bouveault).	103
Aldehyde-Sulphurous Acid Salts ; Constitution of —. (Reinking, Dehnel, and Labhardt).	330
Aldehydic Derivatives ; Production of —. (P) Badische Anilin und Sodafabr.	1300
Derivatives; Production of — and Application as Discharges. (P) Badische Anilin und Sodafabr.	967
Alfa . See Esparto.	
Alimentary Product ; Manufacture of —. (P) Poumay.	746
Product; New —. (P) Soc. Henneberg et ses Fils.	854
Substances; Apparatus for Eliminating Moisture from —. (P) Witschi-Studer.	746
Substances; Sterilisation of —. (P) Nesfield.	39
Substances. See also under Foods.	
Alizarin Assistant ; U.S. Customs Decision on —. (T.R.).	158
Dyestuffs. See Dyestuffs.	
Alkali and Alkaline Earth Carbonates ; Manufacture of — and Apparatus therefor. (P) Polunowsky.	891
and Alumina; Production of — from Alkaline Silicates. (P) Levi.	546
Carbonates, Hydroxides and Polysulphides; Simultaneous Manufacture of —. (P) Germain.	441
Castner Mercury Process for Making —. (Le Blanc and Cantoni).	1021
Caustic; Production of — by Electrolysis. (P) Cassel.	95
Cyanides; Manufacture of —. (P) Cyanide Co.	
From Jacobs, Witherspoon and Thurlow.	546
Heptamolybdates; Iodometric Determination of —. (Glassmann).	211
Hypochlorites. See under Hypochlorites.	
Metal; Recovery of — from Alkali Metal Amalgam. (P) Baker and Burwell.	282
Oxides; Affinity of — for Different Anhydrides. (Gerassimoff).	131
Peroxide; Obtainment of Oxygen from —. (P) Roessler and Hasslacher Chem. Co. from Foersterling and Philipp.	546
Works Bill. (T.R.).	641
Works; Report of Chief Inspector of —. (T.R.).	728
Alkalis and Alkaline Earths ; Reducing Sulphates of — to Sulphides. (P) Castiglioni and Calastretti.	845
Manufacture of Dehydrated Caustic —. (P) Johnson.	731
From The Badische Anilin und Sodafabr.	
Alkaline Earths ; Colloidal Salts of the —. (Neuberg).	1130
Alkaloid of Calycanthus Glaucaus . (Gordin).	1252
of Calycanthus Glaucaus; Crystalline —. (Gordin).	289
Alkaloids of Certain Myrtilac Solanaceous Plants . (Schmidt).	748
Coniine; Separation of the —. (von Braun).	1082
Corydalis; Composition of —. (Gadamer and Haars).	634
Formation of — in Plants. (Pictet).	856
Opium; Constitution of —. (Knorr and Pschorr).	1082
Alkoxy Group ; Influence of — on the Velocity of Saponification. (Findlay and Turner).	564
Alkylapomorphinium Salts ; Production of Easily Soluble, Stable —. (P) Pschorr.	750
Alkylbarbituric Acids . See Barbituric Acids.	
Alkoxyacetylurea , and Preparation of same. (P) Parke, Davis and Co. From Clemmensen and Heitmann.	985
2-Alkoxypprimidines ; Preparation of —. (P) Bayer und Co.	456

Electrolytic —. (Goodwin)	1179	Wicks for —. (P) Pfersdorff	666
Metallic; Examination of —. (Ardit)	93	Canes; Bleaching Rattan — for Chair —.	842
Metallic; Preparation of — for Laboratory Use. (P) (Wöhler)	1022	Caoutchouc; Assay of —. (Esch and Co.)	47
Calcium Carbide as an Explosive in Mines. (Giedras) ..	105	Chemistry of —. (Dittmar)	283
Carbide Industry in France. (T.R.)	863	Decomposition and Constitution of —. (P) —.	148
Carbide Ingots; Utilisation of Scale from —. (P) Union Carbide Co. From Edmunds and Seales ..	612	Extraction of Juices yielding — and —. (P) —.	745
Carbide; Preparation of —. (P) Leinss	235	Extraction of Pure Raw —. (P) von Stechow	1314
Carbide; Production of —. (P) Union Carbide Co. From Price	281	Extraction of Raw — from Rubber-yielding —. (P) von Stechow	1315
Carbide; Regulations on — in Ceylon. (T.R.)	946	From a New Species of Euphorbia. (Jurnelle)	506
Chloroborates; Study of —. (Ouvrard)	968	Nitrosites of — and their Application. (Alexand) ..	231
Cyanamide. (Zielstorff)	554	Obtaining — from Plants of the Nettle Family. (P) Greiff, Tilt and Roscoe. From Reeder	34
Cyanamide; Application of Peat to Conversion of — into Ammonium Compounds. (Perotti)	554	Pre-existence of — in the Latex. (Esch and Chwolson) ..	5
Cyanamide as a Fertiliser. (Perotti)	143	Production of — (from Guayule). (P) Marx	203
Cyanamide; Reactions of — in Agricultural Practice. (Perotti)	1245	Solutions; Production of Aqueous —. (P) Alexander	1214
Nitrate in Agriculture. (Bellenoux)	628	Substitute for —. (P) Spatz	507
Nitrates; Manufacture of —. (P) Price	546	Waste; Regeneration of —. (P) Alexander	1244
Orthophosphate, Mono-; Preparation of —. (P) Burleigh and King	339	Weber's Dinitro —. (Harries)	203
Peroxide; Electric Production of — at Niagara Falls. (T.R.)	947	See also India-rubber and Rubber.	
Phosphate, Citrate-soluble, and Chlorine; Simultaneous Electrical Production of —. (P) Clemm	1067	Cape Colony; Excise Duty on Foreign Spirits in —. (T.R.)	822
Phosphate; Manufacture of Dibasic —. (P) Arcus	628	Trade of — in 1904. (T.R.)	355
Phosphate Minerals; Treatment of —. (P) Gardeur and Gernaert	732	See also Africa, South.	
Silicates; Research on —. (Tischler)	620	Caps for Use with Projectiles; Manufacture of —. (P) Hadfield	291
Sulphate in Ammonium Sulphate Solution. (Sullivan) ..	618	Capsine; U.S. Customs Decision on —. (T.R.)	162
Sulphate; Solubility of — in Sulphates of other Salts. (Cameron and Brown)	618	Carbides, Metallic; Electrical Manufacture of —. (P) Lanhofer and Comp. Cont. d'Electricité Appliquée ..	281
Sulphate. See also Gypsum and Plaster-of-Paris.		Carbinols. See Dyestuffs.	
Calcium-Aluminium Silicates; Research on —. (Tischler) ..	620	Carbohydrates; Action of Hydrogen Peroxide on —. (Morrell and Bellars)	515
Calcepar, Powdered; U.S. Customs Decision on —. (T.R.)	697	Caramchisation of —. (P) Gonville and Jarvis	936
Calender Bowls or Rollers for Finishing Textiles. (P) Hübner and Pope	85	Nitrated; Manufacture of —. (P) Hough	691
Double-acting — for Hot-pressing Tissues. (P) Cocheux	672	Reactions of —. (Adler)	351
Calico Printing; Engraving Copper Rolls for —. (P) Paterson	1225	Solvent for Nitro-derivatives of —. (P) Warner Chemical Co. From Riddle	983
Printing; Use of Formic Acid in —. (Kapil)	129	Carbon of Arc Lamps; Utilisation of the Waste Ends of —. (P) Peters	97
Calicos; Printing of —. (P) Hulme	799	Carbon; Electric Fusion of —. (Braun)	945
California; Petroleum Production of —. (T.R.)	215	Electrodes of Arc Lamps; Utilisation of Waste —. (P) Peters	742
Calomet; New Modification of —. (Meyer)	1254	In Ferro-Silicon; Determination of —. (Jene)	459
Calophyllum Inophyllum Seed; Oil of —. See Oils, Fatty.		Filament; New —. (Howell)	882
Calorimeter; Junker's —. (Immenkötter)	1032	Filaments; Manufacture of —. (P) General Electric Co. From Levis	882
Calycanthus Glauces; Crystalline Alkaloid of —. (Gordin) ..	289, 1252	New Allotropic Form of —, and its Heat of Combustion. (Mixer)	906
Camphene; Production of —. (P) Soc. Gen. pour la Fabr. des Matières Plastiques.	750	In Organic Compounds; Determination of —. (Progl)	562
Camphor from Isoborneol; Manufacture of —. (P) Zimmermann. From Chem. Fabr. vorm. E. Schering	209	Production of Treated —. (P) British Thomson-Houston Co. From Gen. Electric Co.	1230
(P) Johnson. From Boehringer und Soehne ..	249	Relation to one another of Modifications of —. (Sehenck and Heller)	803
Manufacture of —. (P) Boehringer und Soehne. From Aeh	1188	Separation of — and Apparatus therefor. (P) Darling	277
(P) Chem. Fabr. von Heyden. From Seifert and Philipp	150	Separation of — from Carbon Dioxide. (Irruner) ..	564
(P) Chem. Fabr. vorm. E. Schering	902	Specially Suitable for Making Filaments of Electric Lamps. (P) Levis. From Gen. Electric Co.	721
(P) Zimmermann. From the Chem. Fabr. vorm. E. Schering	1188	"Temper"; Nature of —. (Wüst and Geiger)	1112
Preparation of — from the Esters of Isoborneol. (P) Chem. Fabr. vorm. E. Schering	750	Carbon Bisulphide Emulsions, Miscible with Water. (P) Chem. Fabr. in Bihwänder	1027
Synthesis of —. (P) Réhal, Magnier and Tissier	857, 985	Bisulphide; Obtainment of — in Carbonisation of Peat. (P) Augier	1021
(P) Dubosc and Piquet	857	Dioxide in Combustion Gases; Apparatus for Determining —. (P) Schlatter and Deutsch	904
Trade in Japan. (T.R.)	698	Dioxide; Disintegration of Iridium in —. (Enrich) ..	1065
Camphors, Artificial; Manufacture of —. (P) Richardson ..	208	Dioxide; Fixation of — by Amphoteric Ammonio Bodies. (Siegfried)	451
Canada; Bounty on Petroleum in —. (T.R.)	215	Dioxide; Influence of Water Vapour on Reduction of — by Carbon. (Boudouard)	891
Cement Industry Established in —. (T.R.)	355	Dioxide; Manufacture of —. (P) Stead	132
Corundum Deposit in —. (T.R.)	50	Dioxide; Manufacture of Liquid —. (P) Syssoyoff and Cheynet	732
Customs Decisions on Articles Exempt from and Subject to Special Duty in —. (T.R.)	215	Dioxide; Method of Absorbing —. (P) Wulze	845
Duty on White Lead in —. (T.R.)	947	Dioxide; Production of — during Fermentation. (Lindet and Marsais)	145
Iron and Steel Production of — in 1904. (T.R.)	864	Dioxide; Reaction of — on Hydroxides and Carbonates of Alkali and Alkaline-Earth Metals. (Rankow) ..	58
Mineral Production of —. (T.R.)	357	Dioxide; Recovery of — in Treatment of Sulphide Ores, &c. (P) Elworthy and Lance	925

Azo — and Intermediate Products. (P) Newton		963
From Bayer and Co.		
Azo- and Lakes therefrom; Manufacture of — (P) Johnson. From Badische Anilin und Soda-fabr.		128
Azo — and Manufacture of same. (P) Colour Works formerly Geigy. From Hagenbach		664
Azo- —; Manufacture of. (P) Johnson. From Badische Anilin und Soda-fabr.	541,	810
Azo —; Manufacture of. (P) Johnson. From Kalle and Co.		669
Azo —; Manufacture of. (P) Lake. From Oehler		14
Azo —, and Manufacture of same. (P) Metz. From Fourmoux		143
Azo —; Manufacture of. (P) Newton. From Bayer and Co.		1099
Azo —; Manufacture of. (P) Ransford. From Cassella and Co.		84
Azo —; Manufacture of. (P) Shillito. From Colour Works formerly Geigy	725,	964
Azo —; Manufacture of, and of Intermediate Products therefor. (P) Johnson. From Badische Anilin und Soda-fabr.		144
Azo Mordant —; Manufacture of. (P) Lake. From Oehler		38
Azo —; New Direct. (Barbier)		262
Azo — from 6-Nitro-2-Aminophenol; Manufacture of —. (P) Abel. From Actienges. für Anilinfabr.		1298
Azo — from Phenetol. (Lefevre)		132
Azo —; Preparation of. (P) Bayer and Co.	329,	329
Azo —; Preparation of New —. (P) Bayer and Co.	1222,	1222
Azo — suitable for Manufacture of Lakes. (P) Bayer and Co.		1061
Azo — Suitable for Production of Lakes. (P) Johnson. From Badische Anilin und Soda-fabr.		84
Azo —, Suitable for Production of Lakes. (P) Badische Anilin und Soda-fabr. From Julius and Füssenecker		726
Azo-Benzoeic Acids; Benzaldehyde —. (Alway and Bonner)		1009
Azoxonium Compounds. (Kehrmann)	1104,	1297
Benzalacetone, Di-; Preparation of —. (Baeyer)	326,	432
Benzaldehyde-Azo-Benzoeic Acids. (Alway and Bonner)		1009
Benzanthrone —. See Anthracene.		
Benzenecarboxylic Acid. o-Hydroxy-; Phenyl or Naphthyl Ethers of —. (P) Actienges. für Anilinfabr.		346
Benzene Derivatives and Sulphide Dyestuffs therefrom; Manufacture of —. (P) Ransford. From Cassella and Co.		1167
Benzylsulphonic Acid, m-Nitro-o-chloro-; Preparation of —. (P) Meister, Lucius and Brünig		434
Betanaphthol —, and Manufacture of same. (P) Kalle and Co. From Elbel		84
Bisulphite Compound of a Tetrazol- and Manufacture of same. (P) Meister, Lucius and Brünig. From Otto		885
Black Disazo-; and Manufacture of same. (P) Meister, Lucius and Brünig. From Schirmacher		128
Black Monoazo — susceptible to Chroming. (P) Badische Anilin und Soda-fabr.		434
Black Sulphide-; Dyeing unmordanted Cotton. (P) Vidal and Junius		840
Blue; Production of — on the Fibre. (P) Inray. From Meister, Lucius and Brünig		1010
Blue Amino-monoazo-; Preparation of — (P) Meister, Lucius and Brünig		886
Blue Anthracene; Production of —. (P) Bayer and Co.		726
Blue-Black Azo —; Production of —. (P) Shillito. From Colour Works formerly Geigy		1061
Blue-black to Black Sulphur-; Manufacture of —. (P) Cosway and The United Alkali Co.		237
Blue Monoazo; Preparation of —. (P) Badische Anilin und Soda-fabr.		542
Blue Mono-azo-; Production of —. (P) Lake. From Oehler		796
Blue — from New Nitroso Bodies. (P) Ransford. From Cassella and Co.		1297
Blue Sulphide; Preparation of —. (P) Kalle & Co.		434
Blue Sulphide; Differentiation of —. (Lüttringhaus)		638
Blue Sulphide — and Manufacture of same. (P) Badische Anilin und Soda-fabr. From Abel and Lüttringhaus		669
Blue Sulphide-; Manufacture of —. (P) Cosway and The United Alkali Co.		237
Blue Sulphide — and Manufacture of same. (P) Kalle and Co. From Elbel		84
Blue Sulphide, and Manufacture of same. (P) Meister, Lucius and Brünig. From Schmidt and Bethmann		23
Blue, Violet and Black; Manufacture of — by Oxidation on the Fibre. (P) Inray. From Meister, Lucius and Brünig		1225
Brasilin and Haematoxylin. (Herzig and Pollack)		724
Brown — obtained by Combining Substantive Dyestuffs with Different Diazo Derivatives. (Calvert and others)		670
Brown Monoazo — developed by Chroming. (P) Inray. From the Soc. of Chem. Industry, Basle		919
Brown Sulphide — and Making same. (P) Oehler. From Laska		1167
Calico Yellow G and Chrome Grey R.B.G.; U.S. Customs Decision on —. (T.R.)		51

Dyosinns—cont.

Dye-stuffs— <i>cont.</i>	PAGE
Carbinols; Reaction of ———— Decomposition of ———— (von Georgiev)	329
Catechin and ———— Catechin (Perkins)	541
Chlorinated Anilines; Bases and Violet Matter (P. Schütt)	237
Chlorinated Anilines; Meister, Lucius and Brünig	237
Chlorinated Anilines; Manufacture of ———— (P. Schütt)	964
Chloro- and Bromo- ———— Chloride; Preparation of ———— (P. Badische Anilin und Soda-fabr.)	1298
Chloronitrosamine; Manufacture of ———— (P. Schütt)	128
Chromic; Syntetic ———— (V. Braun & St. v. Kostanecki)	325
Chrysazin, &c.; Manufacture of ———— (P. Schütt)	841
Compound ———— (P. Badische Anilin und Soda-fabr.)	841
Compound; New ———— (P. Schütt)	841
Crystal Violet; Action of ———— (P. Schütt)	841
Cyanine ———— (Friedrich and B. Schütt)	841
Cyanine ————; Constitution of ———— (P. Schütt)	1297
of the Cyanine Series; Preparation of ———— (P. Schütt)	1297
for Photographic Purposes ———— (P. Schütt)	1297
for Anilinfabr. ———— (P. Schütt)	1297
and Derivatives from Anthracene; Manufacture of ———— (P. Schütt)	1297
stuffs; Series of New ———— (P. Schütt)	1297
(P) Badische Anilin und Soda-fabr.	1016
derived from Dye-stuffs of the Oxazine Series; Preparation of ———— (P. Schütt)	1016
From Dye-Works formerly Durand, Heilmann and Co.	1016
Diamine; Fuming ———— on Cotton, by the Steam ———— (Justin-Mueller)	494
Diamines; Action of Formaldehyde and Soda on ———— (Friedrich)	193
2,3-Diamino-anthraquinone, and Azines of the Anthraquinone Series. (Schöll & Krieger)	668
1,4-Diaminoanthraquinone, &c.; Preparation of ———— (P. Schütt)	23
(P) Meister, Lucius and Brünig	670
Diaminodiphenylamine Sulphonic Acid, and Manufacture of same. (P) Actienges. für Anilinfabr. From Geldermann	1105
Diazobenzenes and Aminoazo-compounds; Influence of Substitution on Formation of ———— (Morgan, Wootton and Clayton)	795
Diazobenzenes of Diphenylamine, Derivatives of Homologues of Aniline and the Naphthylamines. (Vignon and Simonet)	432
Diazobenzene Compounds; New Synthesis of ———— (Dimitroff)	236
Diazo-amino Compounds; Secondary ———— (Vignon and Simonet)	493
Diazobenzene and Aniline; Limit of Combination of ———— (Vignon)	127
Diazo Compounds; Formation of ———— (Schmidt)	1059
Diazo Compounds of the Naphthalene Series; Manufacture of ———— (P) Colour Works. Formerly Geigy. From Sandmeyer	840
Diazo Derivatives of α -Aminonaphthol Sulphonic Acids. (P) Kalle and Co.	1062
Diazo-Derivatives of Monoacylated Aromatic Diamines. (Morgan and Micklethwait)	723
Diazonium Chloride, <i>p</i> -Nitrobenzene; Rate of Decomposition of ———— (Schwalbe)	724
1-Diazo-2-oxy and 2-Diazo-1-oxy-naphthalene Mono-, Di- and Tri-sulphonic Acids; Manufacture of ———— (P) Schütt. From Geigy	433
Diazo Reaction in the Diphenyl Series. II. Ethoxybenzidine. (Cain)	82
Dibenzylacetone and Triphenylmethane. (Baeyer)	326, 432
Dibromo-1,5-diaminoanthraquinone; Constitution of ———— (Schöll & Krieger)	82
Dibromo- and Dichloromaleic Acid; Some Derivatives of ———— and their Conversion into Indigo. (Salmony and Simonis)	1058
2,6-Dibromo-4,8-dinitro-1,5-dinitraminoanthraquinone; Behaviour of Nitramine Group during Action of Aromatic Bases on ———— (Schöll & Krieger)	82
3,4-Dichloraniline; New Sulphonic Acid of ———— (P) Actienges. für Anilinfabr.	1010
Dichlorodimethylfluorane, and Manufacture of same. (P) Badische Anilin und Soda-fabr. From Julius	328
α - α -Dichloro- β - β -dimaphthylamine. (Schaposchnikoff and Goleff)	724
2,3-Dihydroxyanthracene. (Lagodzinski)	1059
α -Dimethoxyanthraquinones; Preparation of ———— (P) Meister, Lucius and Brünig	615
Dimethylamine <i>p</i> -sulphonic Acid and Azo Dye-stuffs therefrom. (Lefèvre)	192
Dinaphthylamine, α - α -Dichloro- β - β ———— (Schaposchnikoff and Goleff)	724
<i>p</i> -Diphenyloldimethylmethane; Nitro Derivatives of ———— (Székely)	82
Diphenyl; Quinonoid Derivatives of ———— (Wittstätter and Kall)	432
Distributing ———— on Fabrics, and Apparatus therefor (P) Meister, Lucius and Brünig	1168
Eosine; Products of Autoxidation of ———— (Holt)	1222
Erythrohydroxyanthraquinone, &c.; Manufacture of ———— (P) Soc. Bayer et Cie.	841
Ethylaniline; Preparation of Pure Mono ———— (Blume and Klöpper)	1166
Evaporating and Concentrating Waste or Spent ———— (P) Lennox	342
Fisetin; Some Less Highly Hydroxylated Compounds relating to ———— (Berstein, Frasciua and St. v. Kostanecki)	723

Dyestuffs—*cont.*

PAGE

Organic Compounds; Solubility of Some — in Water at Different Temperatures. (Dolinski)	613
Ortho-dioxyanthraquinone Sulpho Acid and Manufacture of same. (P) Hlinsky	721
Ortho-oxazo- from 2-Diazo-1-Naphthol Sulphonie Acids. (P) Shillito. From Colour Works, formerly Geigy	721
Ortho-oxo Azo —; Manufacture of —. (P) Shillito. From Colour Works, formerly Geigy	668
Oxazine and Azine; Manufacture of —. (P) Inray. From Meister, Lucius and Brüning	668
Oxazine Derivatives of the Anthracene Series. (P) Meister, Lucius and Brüning	431
Oxazones; Research on —. (Guehn and Bauer)	1060
Oxyanthraquinone Derivatives; Manufacture of —. (P) Hlinsky and Wedekind & Co.	127
<i>o</i> -Oxyanthraquinones and <i>o</i> -Oxyanthraquinone-oxysulpho Acids; Manufacture of —. (P) Hlinsky and Wedekind & Co.	23
Oxyazo Compounds; Constitution of —. (Teichner)	1167
Phenol, Nitroso-; Preparation of —. (Decker and Solonina)	132
Phenosafranines; Symmetrical and Unsymmetrical —. (Barbier and Sisley)	1296
Phenylglycine Salts; Manufacture of —. (P) Johnson. From Badische Anilin und Sodafabr.	511
1,8-Phenyl- or Tolinaphthylaminesulphonic Acid; Preparation of —. (P) Actienges. f. Anilinfabr.	796
1,6- and 1,7-Phenyl- or Tolinaphthylaminesulphonic Acids; Preparation of —. (P) Actienges. f. Anilinfabr.	796
Polyazo —; Preparation of. (P) Kalle & Co.	1224
Primary Disazo —; Preparation of. (P) Oehler	542
Printing with Direct —. (Wilhelm)	670
Pyrene —; Compounds for Use in Manufacture of —. (P) Johnson. From Badische Anilin und Sodafabr.	493
Pyrrhol Blue; The Group of —. (Liebermann and Häse)	1104
Quantitative Determination of some — in Dyed Cotton Fabrics. (Knecht)	154
Quercetol; An Isomide of —. (St. v. Kostanecki and Rude)	378
Quinizarin; Manufacture of —. (P) Bayer & Co.	796
Quinol, Hydroxy; Condensation of — with Aldehydes. (Heintschel)	1104
Quinoline- (Besthorn and Ibele)	724
Quinone; Imines of —. (Willstaetter and Pfannenstiel)	102
Quinophthalone and its Homologues; Preparation of Pure —. (P) Eibner	796
Red Monoazo —, suitable for Production of Lakes. (P) Badische Anilin und Sodafabr.	84, 329, 433, 434, 726, 964
Red Sulphide —; Preparation of: (P) Anilin-farben Fabr. vorm. Geigy	1223
(P) Meister, Lucius and Brüning	886
Red-Violet Sulphide —; Preparation of. (P) Kalle and Co.	614, 886
Reddish Azo- (P) Bayer & Co. From Krebeler and Blank	796
Resacetin; Three Isomeric Hydroxyl-Homologues of —. (Bülow and Sautermeister)	82
Rhodamines; Manufacture of —. (P) Badische Anilin und Sodafabr.	329
Rhodamines; Research on —. (Noelting and Dzewonski)	1296
Rosaniline Hydrochloride; Colourless —. (Lambrecht and Weil)	22
Rosinduline, Trihydroxyphenyl-; Preparation of —. (P) Kalle and Co.	614, 614, 886
Rosindulines, Hydroxyphenyl-; Preparation of —. (P) Kalle and Co.	886
Safranines, Pheno-; Symmetrical and Unsymmetrical. (Barbier and Sisley)	1296
Sensitising Properties of some New —. (Kieser)	751
Sulphide; Action of Tannin on the Leuco-Derivatives of —. (Justin-Mueller)	965
Sulphide — Black. (P) Holliday and Sons, Turner, and Dean	1167
Sulphide — Dyeing Clear Yellow Shades on Unmordanted Cotton. (P) Meister, Lucius and Brüning	1223
Sulphide — Dyeing Violet-Blue to Blue Shades on Cotton. (P) Badische Anilin und Sodafabr.	24
Sulphide —; Existence and Function of Mercaptan Groups in Direct —. (Vidal)	83
Sulphide; Preparation of —. (P) Soc. ancion. Gilliard, Monnet et Cartier	726
Sulphide; Production of — on the Fibre. (P) Actienges. für Anilinfabr.	618
Sulphide; Fixing — by the Aid of Sodium Hydro-sulphite-Formaldehyde. (Fayre)	797
Sulphide- and Materials for their Production. (P) Abel. From Actienges. f. Anilinfabr.	795
Sulphide; Recovery of — from the Dye-Vat. (P) Schmitt	330
Sulphide-; Manufacture of —. (P) Ransford. From Cassella & Co.	795
Sulphide —. See also Indophenols.	
<i>ω</i> -Sulphomethyl Derivatives of Aromatic Amines; Preparation of —. (P) Badische Anilin und Sodafabr.	797
<i>ω</i> -Sulphomethylantranilic Acid; Preparation of —. (P) Badische Anilin und Sodafabr.	542

Dyestuffs—*cont.*

PAGE

Sulphurised; Manufacture of New —. (P) Abel. From Actienges. für Anilinfabr.	1167, 1167
Terephthalaldehyde —; Thiele's Xylol —.	1104
Thiazol-Sulphonie —; Production of —. (P) Bayer and Co.	1168
Trihydroxyphenyl —; Preparation of —. (P) Kalle and Co.	614
Trihydroxyphenyl —. See above. Anilinfabr.	
Triphenylmethane —; Action of Sulphurous Acid on. (Dürschnebel and Weil)	1200
Triphenylmethane; Influence — Position of Methyl- and Nitro-Groups — on Factorial Properties of —. (Reitzenstein and Rott)	67
Tryphenylmethane, fast to Alkalis. (Lehrfeld)	886
Violet Anthracene — and Manufacture of same. (P) Badische Anilin und Sodafabr.	491
Violet Sulphide; Preparation of —. (P) Kalle and Co.	886
Violet Sulphide; and Manufacture of —. (P) Badische Anilin und Sodafabr.	128
Violet Sulphide — and Manufacture of —. (P) Meister, Lucius and Brüning.	83
Yellow Mordant Azo-; Preparation of —. (P) Meister, Lucius and Brüning	796
Yellow Mordant Monoazo —; Preparation of —. (P) Meister, Lucius and Brüning	512
Yellow to Orange-Yellow Monoazo — suitable for Production of Lakes. (P) Badische Anilin und Sodafabr.	1224
Yellow-Red Azo —. (P) Actienges. für Anilinfabr.	1167
Yellow Sulphide — for Cotton. (P) Meister, Lucius and Brüning	431, 690
Yellow Sulphide — for Cotton; Preparation of. (P) Badische Anilin und Sodafabr.	797
Yellow Sulphide —; Preparation of —. (P) Chem. Fabr. Weiler-ter-Meer	615
Yellow Sulphide; Preparation of —. (P) Oehler	615
Yellow Sulphide —; Production of. (P) Actienges. für Anilinfabr.	541, 1105
Yellow Sulphide —; Manufacture of. (P) Ellis. From Chem. Fabr. vorm. Sandoz	1167
Yellowish-Red Monoazo, suitable for Producing Lakes. (P) Badische Anilin und Sodafabr.	542
Dynamite from Cellulose of Gorse, &c. (P) Horteolomp.	344
Effects of Explosion of — at a Distance. (Thomas)	751
Dynamo Brushes, &c.; Production of —. (P) The British Galvanic Metal Packing Co. From Papier-Fabr.	930

E

Earth found in Alluvial Deposits; Use of — in Ceramic Industry. (P) Dessane	1110
Green —; U.S. Customs Decision on. (T.R.)	698
Earths; Bibliography of the Rare —. (Meyer)	248
Monazite; Separation of —. (Feit and Przibylka)	208
Earthenware; Kilns for Firing —. (P) Reid	198
Ebonite; Substitute for —. (P) Story	1081
Ecdysanthera micrantha, A. De.	1314
Eder's Solution. See Mercuric Oxalate.	
Edinburgh; Visit to —	876
Education; Higher — and Chemical Industry. (Bakley)	1265
Effluents; Apparatus for Mixing Chemicals for Purification of —. (P) Howatson and Boly	242
Distillery or Similar; Purification of —. (P) Hawliczek	901
Suspended Matter in —. (Fowler and Arden)	483
Eggs and Egg-containing Substances in Dry Form. (P) Hatmaker	1319
Egypt; Regulations respecting Importation of Explosives into —. (T.R.)	643
Elder Leaves; Glucoside of Hydrocyanic Acid in —. (Bourquelot and Danjou)	857
(Sambucus nigra); Cyanogenetic Glucoside of the —. (Guignard and Houdas)	939
Electric Arcs; Apparatus for Submitting Gases and Vapours to the Action of the —. (P) Naville and Guye	1178
Arcs; Producing Reactions in Gases by means of —, and Apparatus therefor. (P) Johnson. From the Badische Anilin und Sodafabr.	1178
Discharges; Process for Deviation of —. (P) Thomsen and Tharaldsen	976
Disintegration; Mechanism of —. (Braun)	945
Furnaces. See under Furnaces.	
Insulating Compositions. See under Insulating.	
Electrical Resistance Bodies; Production of —. (P) Thompson. From Chem. Elekt. Fabr. "Prometheus"	243
Resistances; Manufacture of —. (P) The Electric Equipment and Securities, Lim. and Ruzicka	850
Electricity; Thermo-Chemical Generator of —. (P) Basset	1312
Water-Power Required for Generating —. (T.R.)	215
Electrite; U.S. Customs Decision on —. (T.R.)	1041

	Page.
Explosive or Blasting Compounds — <i>cont.</i>	
and Manufacture of same. (P) Müller-Jacobs and Wein-	41
gartner. From Müller-Jacobs	
Materials; Manufacture of — (P) Westfälisch	
Anhaltische Sprengstoffe Actienges.	987
New — (P) de Golovine	1092
Picric Acid Classified as an — (T.R.)	759
Production of — (P) Bichel	132
Explosives; Aluminium in — (Bichel)	1324
containing Aluminium or other Light Metals. (P)	
Haddan. From Roth	811
Cartridge Wrappers for — (P) Soc. Gen. pour la	
Fabr. de la Dynamite	1122
Chlorate; Manufacture of — (P) Thomas	1039
in Coal Mines Order, Aug. 4, 1905	986
in Coal Mines; Statutory Rules and Orders, 1905.	
(T.R.)	643
containing Cyanamide; Obtainment of — (P)	
Cyanid-Ges.	250
Detonating and Propellant — (P) Schulz and Gehre	1032
Dinitro-glycerin — (P) Mikolajczak	318
Factories and Testing Stations; Report on Visits to	
certain — in Belgium, Germany and Holland.	
(Lloyd and Desborough)	939
High — (P) Imperial	1084
Improved — (P) Girard	752
Improvement of — (P) Lake. From Cyanid-Ges.	44
Improvements of — (P) Mitchell	250
Manufacture of — :	
(P) Ceipek	456
(P) Duttenhöfer	105
(P) Gonsalves	1256
(P) Johnson. From Soc. Anou. des Poudres et	
Dynamites	152
(P) Lheureux	250, 1256,
(P) Smith	941
(P) Vergé	348
Manufacture of Safety — (P) Soc. Franc. des	
Poudres de Sûreté	858
Nitrating Apparatus. (P) Gebr. Heine	457
Nitrocellulose; Manufacture of — (P) Hesketh	
and Wilcox	1084
Nitroglycerin; Conditions of Freezing of — (Nauck-	
hoff)	104
Nitroglycerin; Manufacture of — (P) Hesketh	
and Wilcox	984
containing Nitroglycerin; Preparation of — (P)	
Deutsche Sprengstoff Act-Ges.	1256
Nitroglycerin; Preventing the Freezing of — (P)	
Westfälisch-Anhaltische Sprengstoff	903
Perchlorate — (P) Bowen.	250
Prevention of Humidity of — (P) Soc. Gen. pour la	
Fabr. de la Dynamite	1032
Proof of Percussion Caps. (Brownson)	381
Regulations respecting Importation of — into Egypt.	
(T.R.)	643
Report of H.M. Inspectors of —	858
Researches on — (Noble)	940
Safety — (P) The Miners Safety Explosive Co.	
and Levett	44
Safety; Manufacture of — :	
(P) Ceipek	1126
(P) Grobet	903
Safety; Manufacture of Mine-gas-proof — (P) Cas-	
tropier Sicherheitssprengstoff, A.G.	1324
Self-Combustive Compound; Manufacture of —	
(P) Maxim	457
See also Blasting Compounds, Caps, Detonators, Gun-	
Cotton, Gunpowder, Nitro-compounds, Powder and	
Projectiles.	
Export and Import Lists; Alteration in — (T.R.)	110
Extracts; Drying Fluid —, or Blood. (P) Hatmaker	1122
Extraction Apparatus:	
(P) American Extractor Co. From Wheelwright	342
(P) Anderson	1313
(P) Bonnet, Spazin et Cie	339
(P) Lautard	36
(P) Teas	1055
(P) Urbain	1243
(P) Wilson	897
Apparatus; Continuous — (P) Bataille	14

F

Fabric; Figured —. (P) Morton	130
Fabrics made from Animal and Vegetable Fibres; Pro- duction of Oxidation Black on —. (P) Kuntzer	85
Apparatus for Bleaching —. (P) y Rovira	543
Apparatus for Dyeing — in the Piece. (P) Cadgène	124
Apparatus for Producing Designs on Flexible —. (P) Herzog	274
Apparatus for Treating — with Fluids. (P) Gebauer	139
Apparatus for Treating Tubular — with Liquids, &c. (P) Smith	887
Apparatus for Washing, Dyeing, &c — in the Piece. (P) Cadgène	24
Blocks for Embossing or Printing —. (P) Rondet	617

Fabrics—<i>cont.</i>	PAGE
Composition for Alleviation of Metallic P. — (P) P. —	87
Composition for — (P) — (P) American —	1122
Facturing Co. — (P) — (P) —	617
Decorations of — (P) — (P) —	25
Degreasing — with the aid of the Solvent — (P) —	60
Discharging Pastes for Dyeing Textile — (P) —	118
— from Badly-dyed and Soda-fabr. — (P) —	438
Distributing Dyes— (P) — (P) —	727
Dyeing with Halogenated Bodies: Discharges on — (P) —	36
Manufacture of Coloured — (P) — (P) —	438
Manufacture and Waterproofing — (P) — (P) —	727
Metallising — by Electrolysis — (P) — (P) —	438
— Tourchamhoff — (P) — (P) —	727
Method and Means for Producing a High Degree of Gloss on — (P) — (P) —	1196
Oiling of — (P) — (P) — (P) —	138
Printing on — with Nitrocellulose. (P) — (P) —	1107
Printing on Vegetable or Animal — (P) — (P) —	739
Printing of Woven — (P) — (P) —	1107
Roller Machines for Printing — (P) — (P) —	365
— Platt and Smith — (P) — (P) —	698
Factice; U.S. Customs Decision on — (T.R.) —	1088
Factory Act Regulations for Locomotives and Wagons (T.R.) —	1088
Fagara Octandra; Oil of the Wood of —. See Oil, Essential.	
Falence; Definition of — Suggested. (Burt) —	13
Fan or Exhauster for Electrification of Air or Gases. (P) de Mare. —	520
Farina; Sieve for Extracting — (P) — (P) —	622
Fat; Apparatus for Separating — from Wool-waters. (P) — (P) —	141
in Butter; Determination of — (Hesse) —	47
Carbon Tetrachloride as a Solvent for Extracting — from Bones. (Brückel) —	551
Extraction of — from Seeds or Oleaginous Fruits. (P) — (P) —	97
Recovery of — from Sewage, Effluents &c. (P) — (P) —	741
Removal of — from Wool, Hair, &c. (P) — (P) —	129
Fats; Active Products for Enzymic Hydrolysis of — (P) — (P) —	124
Apparatus for Determining Melting Points of — (Ubbelohde) —	941
Apparatus for Extraction of — (P) — (P) —	124
Apparatus for Rendering or Reducing — (P) — (P) —	34
— (P) — (P) — (P) —	124
Bromine Absorption Value of — (Telle) —	29
Enzymic Decomposition of — (Hoyer) —	977
(P) — (P) — (P) —	141
Hydrolysis of — by means of Steam. (P) — (P) —	1074
Investigation of Insolated and Rancid — (Winckel) containing Iodine and Sulphur; Preparation of — (P) — (P) —	857
Manufacture of Solid — from Refinery Residues. (P) — (P) —	102
Material for Saponifying —, from Castor-Oil Seeds. (P) — (P) —	28
Preparation of Stable Iodine or Bromine Substituted — (P) — (P) —	807
Purification of — (P) — (P) —	111
Regeneration and Purification of Waste — (P) — (P) —	851
Synthesis of — (P) — (P) —	62
— and Urbain — before Saponification. (P) — (P) —	89

Fibres—cont.	
Viscose-coated: Manufacture of — (P) Pettit.	727
From Waite	727
Waterproof Viscose-coated, and Manufacture of same.	727
(P) Pettit. From Waite	727
Fibrous Compositions: Vulcanised Binding Medium for	1118
Material: Apparatus for Washing, Dyeing, &c. — (P)	435
(P) Dawson. Apparatus for Dyeing, &c. — (P)	905
Materials: Apparatus for Feltting — (P) Marks.	887
Materials: Apparatus for Washing and Rinsing —	617
(P) Bernhard	617
Materials: Producing Designs on both Sides of —	1228
(P) Moore	1228
Materials: Retting or Preparing — (P) Hunter.	965
Moser and Burrows	334
Materials: Solution for Treatment of — (P) Gare	348
Matter: Nitration of — (P) Solway	437
Shock: Retting of — (P) Brooks and Cutlin.	92
From Lapeau	125
Substances: Impregnation of Fibrous — and Appara-	882
therfor (P) The Electric Timber-Seasoning	885
Preservation Co. and West	190
Filament: Indestructible — for Heating and Lighting.	720
(P) Michaud and Delasson	830
New Carbon — (Howell)	1220
Filaments for Electric Lamps. (P) Levis. From General	533
Electric Co.	431
for Electric Lamps: Machines for Treating — (P)	613
British Thomson-Houston Co. From General	960
Electric Co.	1170
of Electric Lamps: New Form of Carbon for — (P)	963
Levis. From General Electric Co.	
for Incandescent Electric Lamps:	
(P) Crawford	
(P) Just and Hanaman	
(P) Carleton. From General Electric Co.	
for Incandescence Mantles. (P) Just and Hanaman	
Indestructible — for Lighting and Heating. (P)	
Michaud and Delasson	
Manufacture of — from Viscose. (P) Ernst	
Filling Material: Manufacture of a — (P) The Solway	
Process Co. From Pennock	
Material: Production of — (P) Solway Process Co.	
From Sundstrom	
Films, Photographic — See under Photographic.	
Plastic, Transparent Substance for Manufacture of —:	
(P) Cathelineau and René	
(P) Cathelineau and Fleury	
Filter. (P) Kiefer	
Centrifugal — for Wort. (P) Brauerei Gross-Crostitz,	
A.-G.	
Drum — for Paper Factory Waste. (P) Füllner	
Element for — (P) Hartmann	
formed of Fibrous Materials. (P) Stavenhagen	
Improved — (P) Liebrich	
with Inclined Division Plates, for Milk. (P) Baechler	
for Mixed Liquids. (P) Small and others	
Pressure —, for Slimes. (P) Prichard	
Filters:	
(P) Bouff. From Goldman and Co.	
(P) Breyer and von Wehrstedt	
(P) Howatson and Boby	
(P) Lemux	
(P) Seitz	
(P) Schleich	
Beers: Use of Aluminium for — (Schönfeld)	
for Sugar-Juices: Sand — (P) Kostalek	
for Water, &c. (P) Chamberland	
Filter-Beds for Sewage, &c. (P) Adams	
Filter-Press:	
(P) Niles-Bement-Pond Co. From Halschek	
(P) Shaver	
(P) Thompson	
Filter-Press Frames. (P) Meura	
Filter-Presses: Filter Element for — (P) Fromme	
Removing Solid Material from Containers of — (P)	
Merrill	
Trays for — (P) Lawrence	
Filtering Apparatus:	
(P) Dryfus and others	
(P) Johnson and Co. From Johnson	
(P) Kiefer	
(P) Reeves and Bramwell	
(P) Rider	
(P) Seig	
Material (for Water, and Production of same. (P)	
Löffler and Weide	
Materials: Apparatus for Cleaning — (P) Dobson	
Safety Tanks of Vessels used in — (P) van Wester-	
lofz	
Finishing Materials: Preparation of — from Molasses. (P)	
Kowalek	
Fire Buds: Oil of Scotch — See Oils, Essential.	
Oil of Siberian — See Oils, Essential.	
Fire and Acid-Resisting Plates, &c.: Manufacture of —	
(P) Fiesch	

Fire—cont.	
Apparatus for Producing Gaseous Mixture for Ex-	
tinguishing — (P) Marot	151
The Mechanics of — (Armstrong)	153
Firebrick ; Action of Blast-Furnace Gases on — (Lud-	
wig)	156
Composition. (P) Anderson	162
and Dinas Brick in the Construction of Refractory	
Furnaces. (Leisser)	163
Manufacture of —	
(P) Hayt	168
(P) Klein	167
Peculiar Action of Soluble Salts on — (Seeger and	
Cramer)	171
Refractoriness of some American — (Weber)	174
Fireproof Coatings. (P) Eymor and Eymor Ges.	176
Material. (P) Marga	176
Sheet; Manufacture of Fibrous — (P) Watson	176
Fireproofing Compound for Textiles. (P) Lindsay	191
Compound, for Wood. (P) Patten	1173
Firing with Coal-Dust. (Carey)	369
Fisetin. See Dye-stuffs.	
Fish-Liver Oils. See Oils, Fatty.	
Flash-light Cartridges for Photography. (P) Lüttke and	
others	219
Flash-lights ; Powders for Use as —	
(P) Krebs	219
(P) Lüttke and others	219
Flash Testing Apparatus. (P) Fiske Bros. Refining Co.	
From Courtois	987
Flavanthrene ; Printing with — (P) Huray. From	
Meister, Lucius and Brüning	194
Flavinduline. See Dye-stuffs.	
Flavonol, 3'-Hydroxy-. See Dye-stuffs.	
Flax ; Bleaching of — (P) Gagedois	344
Retting of — (P) Vansteenkiste and Legrand	1061
Treating — to Facilitate Bleaching. (P) de Keu-	
kelaere	616
Water-Retting of — (Störmer)	84
Floor-Cloths ; Manufacture of — (P) Smith	682
Floor-coverings ; Manufacture of — (P) Lactoleum	
Werke Ges.m.b.H.	1118
Floors ; Material for Covering — and Manufacture of	
same. (P) Deutsche Bodenbelag-Ges. Stegmeyer	
and Maurer	30
Flosses, Vegetable, or "Silk-Cottons" ; Indian	1299
Flour ; Bleaching of — (P) Shackleton	341
Bleaching of — and Apparatus therefor. (P) Le-	
perche and others	632
Bleaching and Sterilising — (P) Leatham	341
Influence of Ozone on Properties of — (Brahm)	39
Process and Apparatus for Conditioning — (P) The	
Ozonised Oxygen Co. From Merrier	982
Restoring certain properties to White — (P) Roberts	
Treatment of — with Carbon Dioxide, &c. (P)	
Eybert	1027, 1319
Wheat; Testing — for Commercial Purposes. (Snyder)	
.....	1026
Fluavil from Sumatra Gutta-Percha. (Tschirch and Müller)	
.....	627
Flue-dust ; Utilisation of — (P) Price	849
Utilisation of — in the Blast-Furnace. (Attix)	278
Fluids ; Apparatus for Separating Solids from — (P)	
Evans	1190
Apparatus for Testing — (P) Milne and O'Connor	
Heating or Cooling — (P) Proctor and Morgan	663
Fluorane, Dichlorodimethyl-. See Dye-stuffs.	
Fluorescent Screens ; Regeneration of — (Bordier)	1039
Fluorine and Silica ; Separation and Determination of —	
(Seemann)	815
Fluorspar ; Rapid Valuation of — (Gregory)	1127
in the United States. (T.R.)	158
Phosilicates, Alkaline ; Manufacture of — (P) Reich	620
Food for Animals ; Product for Use as — (P) Living-	
stone. From Stein	1249
Milk — for Infants. (P) Hatmaker	981
Preparations; Manufacture of — (P) Bloom	1122
Preservation of — (P) Breckwoldt	117
Product; Manufacture of a — (P) The Organose	
Co.	1122
Products; Bleaching and Sterilising — (P) Leatham	
Products containing Iron; Preparation of — (P)	
Anfsberg	207
Products; Sterilisation of — (P) Ohlson	632
Rendering — Radio-active. (P) Lieber	537
Sterilisation of —	
(P) Budde	510
(P) Krause	147
(P) Thorp	341
Substances; Preserving Animal — (P) Fuida	1080
Foods ; Electrolytic Separation of Arsenic from Liquid —	
(P) Overbeck	1027
(P) Hatmaker	632
See also under Alimentary Substances.	
Foodstuff ; Fatty — (P) Bloom	341
Foodstuffs ; Application of Freezing in Preparation of —	
in Japan. (Katayama)	654

Foodstuffs—cont.	
for Cattle; Mixture of — (P) B. and	
Stevens	851
Dehydrating — Apparatus therefor. (P) Cooke	
and Kelly	1319
Drying Vegetable — (P) Zündel-Bonatti	1319
Gelatinous; Preparation of — (P) Wolf	39
the Thuringian — (P) Jetter and K.	514
Salicylic Acid in — (P) Zündel-Bonatti	514
(Harry and Menzies)	297
Sterilisation of — (P) Preisz	297
Vegetable; Preparation of Salts of the Organic Phos-	
phorus Compound containing — (P) Postel-	
nik	341
Formaldehyde ; Action of — on Pyridine. (Formanek)	691
Colorimetric Method for Detection and Determination	
of — (Bonnet)	289
Commercial Preparation of — (P) M.	151
Detection of — in Spirit Distillation with Formalin.	
(Lindet)	690
and Dextrin; Preparation of — (P) Busch	754
Gasometric Determination of — (P) H. and	
West)	343
Generation of — (Walker)	1043
Hydrogen Peroxide Method of Determination of — (Hag-	
wood and Smith)	213
Methyl Alcohol in; Determination of — (P) M. and	
Kauffer)	1086
Modification of Hehner's Test for — (Lyons)	1626
and Organic Nitrogen Compounds containing —	
Sensitive Reaction of — (Voisen)	690
Preparing Compounds of — with Amides of M.	
basic Acids. (P) Einhorn	901
Product (Disinfectant), and Making same. (P) Black-	
more	902
Production of Formates from — (Euler)	1187
Studies on — (Auerbach and Barschall)	636
Study of Methods for Determination of — (Williams)	
Synthesis of — (Chapman and Holt, jun.)	792
Thermal Decomposition of — (Bone & Smith)	792
See also Formal.	
Formaldehyde-Sulphoxylate (Discharging Compound). (P)	
Badische Anilin und Sodafabr. From Bazlen and	
Wohlfahrt	841
Formalin in Milk ; Detection of — (Utz)	752
Analysis of — (Orloff)	348
Formates ; Production of —	
(Euler)	902
(P) Johnson. From Koepf and Co.	150
Quinine; Preparation of — (Lacroix)	902
Formic Acid ; Application of — in Wool Dyeing. (Mettner)	
Manufacture of Concentrated — (P) Hamel	434
Purification and Determination of — (Rupp)	289
Use of — in the Distillery. (Lange)	353
Use of — in Dyeing and Printing. (Kapff)	1025
Formol ; Commercial Preparation of — (Morel)	129
Forselles Process of Iron Metallurgy	289
Fountains Abbey ; Visit to —	92
France ; Alcohol Statistics for 1904. (T.R.)	875
Calcium Carbide Production in — (T.R.)	299
Cement Production of Lyons in 1904. (T.R.)	863
Chemical and other Industries of Lyons — in 1904.	
(T.R.)	1041
Chemical Trade of Bordeaux in 1904. (T.R.)	1040
Customs Decision on the Alcohol Tax in — (T.R.)	695
Fertilisers Imported through Marseilles. (T.R.)	254
Leather Industry of Lyons in 1904. (T.R.)	848
Minette Iron-Ore District of — (T.R.)	1043
Oil Seeds and Seed Oils in — (T.R.)	1264
Sugar Crop of — (T.R.)	51
Taxation of Methyl Alcohol in — (T.R.)	1135
Fremy's Reagent for Detection of Sodium Salts; Modifica-	
tion of — (Bougault)	254
Friedrichshütte ; Huntington-Heberlein Lead Smelting	
Process at — (Bierbaum)	636
Fructose ; Methylphenylhydrazine Reaction of — (Neu-	
berg)	1112
Fruit Juices ; Preparation of Non-Alcoholic — (P) Stern	
Preservation of — (P) California Concentrated Fruit	
Co. From Sherman	46
Product; Preserved — (P) California Concentrated	
Fruit Co. From Sherman	692
Fruits ; Acidity of — (Sutherst)	853
Drying of — (P) Hatmaker	1080
Preserving — by means of Dry Sugar. (P) Grenard)	1249
Fucose Phenylsazone. (Mayer and Tollens)	1249
Fuel , Agglomerated; Manufacture of —	
(P) Hocke and Heine	1131
(P) Mors and Nobécourt	492
Agglutinants for Use in Solidifying Pressed — (P)	
Middleton	491
Apparatus for Making Artificial — (P) Davis	1164
Artificial —	
(P) Bayles	324
(P) Grayson	836
(P) Hartbridge	1066
(P) Herheim	78
(P) Höpfer	124
(P) Meeker	124

—: —		Detection and Determination of Bituminous Substances in — (Pontio)	460
—: —		Extraction of Juices yielding — and Apparatus therefor. (P) Giovetti and others	743
—: —		from German New Guinea. (P) Tschirch and Müller	627
—: —		Notes on — (Caspari)	1274
—: —		Substitute; U.S. Customs Decision on — (T.R.)	520

<i>Gutta-Percha—cont.</i>	
Sumatra; Albans and Fluavil from —. (Tschirch and Müller)	27
Trade of Singapore. (T.R.)	222
See also Bakata.	
Gynocardia Olorata; Constituents of the Seeds of — (Power and Barrowcliff)	341
Gynocardin; a New Cynogenetic Glucoside. (Power and Lees)	35
Gypsum; Furnace for Calcining —. (P) Kōneman ..	0
Influence of — on Starch and Albumin Conversion in Mashing. (Windisch and Boden)	9
Manufacture of Crystalline —. (P) Brothers	210
Treating — so as to Obtain as desired a Slow- or a Quick-Setting Plaster. (P) Perin	149
Utilisation of Dead-burnt —. (P) Heintzel and Cramer	674
Use of — for Obtaining Textile Material, &c. (P) Boy	1169
See also Calcium Sulphate and Plaster of Paris.	

H

Haddon Hall and Chatsworth; Visit to —	872
Haematoxylin. See Dyestuffs.	
Hair, Artificial; Preparation of — from Casein. (P) Todtenhaupt	1063
Dyeing Human — with Paraphenylenediamine, &c. (P) Guesquin	23
Dyeing and Secretage of — by Spraying. (P) Pichard	1227
Hairs; Dyeing of —. (P) Abel. From The Actienges. für Anilinfabr.	331
Halogen Tertiary Butyl Alcohol. See under Alcohol.	
Halphen's Reaction for Cotton-Seed Oil; Investigation of —. (Fischer and Peyan)	202
Hamburg; Graphite Trade of —. (T.R.)	1328
Hardwickia Binata; Oleoresin of —	689
Hargreaves Process for Manufacture of HCl; Study of the —. (Staedel)	439
Harmaline; Characteristics of —. (Fischer and Buck) ..	149
Harmine; Characteristics of —. (Fischer and Buck) ..	149
Hawaiian Islands; Sugar Production of the —. (T.R.) ..	568
Hayti; Logwood Exports from —. (T.R.)	696
Heat-Insulating Materials; Manufacture of —:	
(P) Jenequel and Hayn	499
(P) Thomain and Gohier	1218
Heat Insulation; Notes on —. (Hutton and Beard)	802
Means for Producing — by Chemical Reaction. (P) Partl, Károlyi and Paats	105
Non-conducting Compositions. (P) Lake. From Soc. Anon. Matthey and Co.	850
Non-conducting Material. (P) Müller and Jarck	848
Non-conducting Material; Manufacture of —. (P) Henke	848
Heating Apparatus:	
(P) Davis	77
(P) Mathieson	1216
(P) The Schoenberg Electric Appliance Co.	896
Apparatus; Electrical —. (P) Electric Moulding and Heating Co.	36
Apparatus for Use in Sugar Manufacture and Refining. (P) Soc. Anon. des Constructions Mecan. de St. Quentin	507
by Chemical Reaction; Compositions for —. (P) Bamberger and Böck	124
Composition:	
(P) Bamberger and Böck	1164
(P) Fireless Heating Co. From Kafka	190
Drum. (P) Maschinenbau-Anstalt, Breslau	881
by Electricity. (P) Voelker	446
Materials, Crucibles, &c., by Gas. (P) Reece	537
by means of Substances having High Ignition Points. (P) Lang	665
Substances in a Vacuum at Constant Temp.; Apparatus for —. (Hodgkinson & Coote)	560
Hehner's Test for Formaldehyde; Modification of —. (Lyons)	1086
Hemp; Bleaching of —. (P) Gagedois	344
Heptadecylic Acid; Investigation of Natural Occurrence of —. (Holde)	447
Heptanaphthene (Methyleyclohexane) and its Derivatives. (Markownikow)	919
Hexahydrothymol; Menthone derived from —. (Brunel) ..	455
Hexamethylenetetramine; U.S. Customs Decision on —. (T.R.)	255
Hexanes; Iso — in Roumanian Petroleum. (Poni & Costachesco)	126
Heusler's Magnetic Alloys. (Hill)	1237
Hide-Powder; Rapid Detection of Cellulose in —. (Kopecky) ..	639
U.S. Customs Decision on —. (T.R.)	464
Hides and Skins; Bating. De-acidifying and Oxidising —. (P) Amend	744
Tanning of —:	
(P) Baron and Aubert	284, 1181
(P) Sonoff and Zwerhoff	98

Hides and Skins	
Treatment of — (P) Oakes	1023
Treatment of — or Partially De- (P) Southwold	627, 979
Weighing of —. (Parker and)	662
Holland; Chemicals of —. (T.R.)	695
Homocel; Properties — as a Sensibiliser. (P) Mees & Sh	857
Honduras; Discovery of — in Yoro	697
Hops; Oil of —. Essential.	
Sulphuring —. Avoid Contamination. (P) Arsenic. (P)	110
Horn; Cellulose Xanthate Substitute for —. (P) Soc. Franç. de la	75
Manufacture of Cellulose —. Imitation of —. (P) Bidier	855
Substitute for —. (P)	1081
Horny Matters; Treatment of —. Notelle and Leroux	450
Horschair, Artificial; Manufacture —. (P) Crespin	543
(P) Verein. Glanzstoff-Fabr.	856
Humic Compounds; Agricultural Value of —. (P)	245
Humid Materials; Apparatus for Experiments with —. (P) Higginbottom and	235
Humus; Treatment of — for Fertilising —. (P) Roux and Gobin	339
Hydnocarpus Wightiana and Hydnocarpus Andrieuxii; Constituents of the Seeds of —. (P) Barrowcliff)	741
Hydrate Theory of Solutions; Application to Electrolytes of the —. (Lowry)	693
Hydraulic Binding Agent from Granulated Slag and Quicklime. (P) Renfert	1018
Press. See under Press.	
Hydrazides; Determination of —. (Maselli)	818
Hydrazine; Determination of — by Mercury Salts. (Ebber) ..	1257
Hydrazine Dyestuffs. See Dyestuffs.	
Hydrazones derived from <i>p</i> -, <i>m</i> -, and <i>o</i> -Nitrophenylhydrazine. (van Eckenstein and Blanksma)	639
Hydrides, Alkali or Alkaline-Earth Metal; Production of —. (P) Darlington. From Machalske	1066
Hydro-Extractor:	
(P) Bök	1162
(P) Cantley	799
(P) Wilson	897
Hydrobromic Acid; Manufacture of —. (P) Hoppe ..	925
Hydrocarbons, Aromatic; Oxidising Methyl Groups in —. (P) Badische Anilin und Soda Fabr.	151
From Bazen and Labhardt	
of the Benzene Series; Electrolytic Oxidation of —. (Law and Perkin)	32, 805
Drying — and Apparatus therefor. (P) Wilke and Co.	723
Enriching —. (P) Phillips	429
Liquid; Burning of —. (P) Davies	79, 79
in Louisiana Petroleum. H. (Coates and Best)	1165
containing the Methyl Group. (Law and Perkin) ..	32
Oxidation and Distillation of —. (P) Soc. Anon. des Combustibles Industriels	668
Production of — with Elimination of Sulphur. (P) Blackmore	127
Purification of —. (P) Fresenius	1117
Solidification of —. (P) van der Heyden	236, 326
Solidified —. (P) Denayronze	429
Sulphurised; Obtainment of —. (P) Comp. Morana ..	750
Unequally Volatile; Distilling and Separating —. (P) Baudry	1008
Hydrochloric Acid Gas; Muffle-Furnace for Manufacture of Concentrated —. (P) Oehler	1109
Acid; Manufacture of —:	
(P) Bosnische Elektrizitäts Actienges.	722
(P) Electric Reduction Co. From Gibbs	132
(P) Everette	1303
(P) Hoppe	925
Acid and Potassium Permanganate; Reaction between — in Presence of Ferric Chloride. (Brown) ..	275
Acid and Sulphuric Acid; Making — and Separating same. (P) Askenasy and Mngdan	1239
Acid; Study of the Hargreaves Process for Manufacture of —. (Staedel)	439
Acid; Table for Preparation of Normal — according to Sp. Gr. (Kuster and Münch)	210
Hydrocyanic Acid and Cyanides; Manufacture of —. (P) Davis	90
Manufacture of —:	
(P) Feld	801
(P) Wolterbeck	1066
Modification of Methods of Liebig and of Förlde and Gelstorf. Determination of —. (Günn)	1258
Phenolphthalein as a Reagent for —. (Weehuizen) ..	562
and Steam; Influence of Contact Substances on the Interaction of —. (Forbes Carpenter & Linder) ..	63
Treatment of Ferrocyanides for Obtainment of —. (P) Bloxam. From Tcherniac	545
See also Prussic Acid	
Hydroferrocyanic Acid; Compounds of Sulphuric Acid with —. (Chrétien)	843

	PAGE
Insects; Means and Product for Destroying — (P) Jenkner and Ployl	101
Insulating Compositions: Electric — (P) The British Thomson-Houston Co. From The Gen. Electric Co.	201
Compositions; Manufacture of — (P) Lake. From Soc. Anon. Matthey and Co.	850
Material, Electrical; Manufacture of — (P) Billwiller and Fabrik Dr. P. Karrer	730
(P) Gen. Electric Co. From Emmett	1240
(P) Marga	136
(P) Müller	730
(P) Sharkey	1072
Material; Electrical — (Porphyrine). (P) Parville	896
Material; Electrical — and Preparation of same. (P) Boitelet and Spiegel	1240
Material for Electro-technical Purposes. (P) Rudenick	1178
Material; Impermeable, Incombustible — (P) Marga	446
Material, and Preparation of same. (P) Meyenberg ..	1342
Materials; Manufacture of — (P) Pontite, Lim. and de Pont	281
Insulators, Earthenware; Manufacture of High-Potential — (P) Locke	673
Inula Graveolens; Oil of —. See Oils, Essential.	
Iaulin; Manufacture of — (P) Stein and Loewenthal ..	744
Manufacture of — from Arctiocke Roots. (P) Gailhat	245
Invar; U.S. Customs Decision on — (T.R.)	1195
Iodates; Reduction of — (Jannasch and Jahn)	637
m-Iodin-o-oxyquinoline- <i>ana</i> -sulphonic Acid readily Soluble in the Stomach. (P) Griese	1188
Iodine; Bromine and Chlorine in —; Determination of Small Quantities of. (Tatlock and Thomson) ..	187
Separation of — from Bromine and Chlorine in Mixtures. (Wentzki)	561
in Soluble Iodides, &c.; Determination of — (Ditz and Margosches)	45
Titration; Benzene as an Indicator in — (Schwezew)	201
Iodoform; Decomposition of — by Combined Action of Light and Oxygen. (van Aubel)	103
Determination of — (Utz)	353
Preparation of — and Apparatus therefor. (P) Elworthy and Lance	1083
Production of — Electrolytically, from Acetone. (Roush)	1253
Iodophenol-formaldehyde Compounds; Preparation of — (P) Henschke	747
Iodoxy Compound, and Manufacture of same. (P) Meister, Lucius und Brüning. From Liebrecht	104
Ionone, α - β -Methyl- — and Manufacture of same. (P) Schmidt	150
Pseudo-; and its Derivatives; Perfumes from — (P) Alexander	750
Pseudo-; Perfumes having the Odour of Violets from — (P) Alexander	750
Iridium; Disintegration of — in Carbon Dioxide, and Dissociation of the Gas. (Emich)	1065
Production of Metallic — (P) Parker-Clark Electric Co. From Parker	1310
Separation of — from Platinum. (Quennessen)	904
Iridium Chloride; U.S. Customs Decision on — (T.R.) ..	1044
Iron; Action of Silicon Chloride on — (Vigouroux) ..	1308
Action of Slightly Alkaline Waters on — (Cribb and Arnaud)	848
and its Alloys; Effect of Liquid Air Temperatures on Mechanical and other Properties of — (Dewar and Hadfield)	199
Apparatus for Manufacture of — (P) Moore and Heskett	32
British Production of — (T.R.)	463
Case-hardening of — (P) Lamargese	623
(P) Lecarme	549
Cast-; Case-hardening of — (P) Lecarme	549
Cast-; Manufacture of — and Apparatus therefor. (P) Levoz	975
Cast-; Soldering Paste for — (P) Herzog	624
Cementation of — (P) Davis	1073
Chromiferous; Treatment of — (P) Campbell ..	893
Consumption of — in Germany. (T.R.)	642
Determination of Small Quantities of — (Leather) ..	385
Electro-deposition of Cadmium on — (Fischer) ..	34
Extraction of — from its Minerals. (P) de Laval ..	1311
Ferrous; Titration of — with Permanganate. (Baxter and Trevert)	988
Furnace for Treating Sheet — (P) Goodsell	94
Hardening of — (P) Bailey. From Ramon	336
Hardening and Cementing — (P) Soc. Cyanid Ges. Hoop; Hardening of — (P) Krauschneider ..	678
Industry of Southern Russia. (T.R.)	51
Influence of Nitrogen on — (Braune)	972
Influence of Nickel and Carbon on — (Waterhouse) ..	1068
Ingot-; Decoxidation of — (P) Elektrostaht Ges. m. b. H. From Eichhoff ..	1175
(P) Imray. From The Soc. Anon. pour l'Industrie de l'Aluminium	335
anitable for Malleable Castings; Production of — (P) Zenzes	444

(P) Th.	1070
Manufacture of — Electrically. (Harbord and Hatch) ..	129
Metallurgy; Process of — (T.R.)	92
Mines in Tunis. (T.R.)	1042
Objects; Electric Case-Hardening of — (P) Kryptol-Ges.	447
Obtainment of — from its Ores. (P) Peacock	148
Ores. See under Ore.	
Pig-; British Production of — (T.R.)	518
Pig-; Copper, Cobalt and Nickel in American — (Campbell)	1059
Pig-; Production of — in America. (T.R.)	303
Pig-; Production of — in Canada. (T.R.)	356
Pig-; Production of — in Canada for First Half of 1905. (T.R.)	946
Pig-; Production of — in the United States in 1904. (T.R.)	216
Pig-; Production of — in the United States. (T.R.) ..	946
Pig-; Purification of — (P) N.	445
Phenomena Accompanying the Reduction of — (Scheneck and Heller)	803
Preparation of Electrolytic — (Maxim-Gisch) ..	140
Process and Apparatus for Making Castings of — (P) Marconnet	804
Production of Canada in 1904. (T.R.)	864
Production of Refined — and Furnace therefor. (P) Thiel	1020
Rapid Cementation of — (P) Lecarme	1177
Recent Advances in the Electro-Metallurgy of — (Hutton)	559
used for Rivets; Effect on — produced by Riveting — (Frémont)	848
Rusting of — (Dunstan, Jowett and Goulding) ..	1235
Rusting of — Dunstan, Jowett and Goulding's Paper on — (Divers)	1235
and Silicon; Compounds of — (Guertler and Tammann)	1236
Silicon in; Determination of — (Morgan)	692
Silicious Pig-; Effect of Sulphur on — (Ward and Longden)	186
Smelting or Reduction of — (P) Zohrab	1019
Sponge; Furnace for Manufacture of — (P) Gröndal ..	1019
Sponge; Production of Wrought — (P) Reynolds ..	1070
Sulphur in; Determination of — (Petrén)	1191
Sulphur in; The Wiborgh Test for — Using a Filter. (Silverling)	106
Surfaces; Removing Copper and Nickel from — (P) Hodkinson	1309
Trade Statistics of Sweden for 1904. (T.R.) ..	1090
Uniting or Coating — with other Metals. (P) Davies and Clark	1309
Wastes; Briquettes of — for Reduction in Furnaces. (P) Rouse and Cohn	501
Wrought —; Crystallisation of. (Arnold)	972
Iron Compounds; New Class of — (Hauser)	1130
Hydride Paint; Manufacture of — (P) Gesner	448
Salts; Oxidation and Reduction Processes in the Electrolysis of Solutions of — (Karaglanoff) ..	930
Sulphides; Formation of — by Dry Methods. (Geddel) ..	674
Sulphides, and the Purification of Coal Gas by means of Ferric Hydroxide. (Geddel)	664
Oxide; Apparatus for Reduction of — (P) Steuart. From Galbraith	933
Oxide as a Gas-Purifying Agent, and its Validation. (Greville)	1101
Oxide; Preparing Fine Particles of — for Use in Furnaces. (P) Wedge	1113
Oxide; Preparing — for Use in Blast Furnaces. (P) Wedge	1310
Oxides; Influence of Water Vapour on Reduction of — by Oxides of Carbon. (Boudouard) ..	92
Pyrites Briquettes, and Manufacture of same. (P) Wedge ..	200
Pyrites Charge for Desulphuring Furnaces. (P) Wedge	1302
Pyrites; Preparing — for Desulphurisation. (P) Wedge	1302
See also under Ferric and Ferrous.	
Iron-Pepton or Iron-Manganese-Pepton; Production of a Stable Non-alcoholic Solution of — (P) Chem. Fabr. Helfenberg	43
Iron-Cyanogen Compounds. See Dye-stuffs.	
Iron-Sand; Apparatus for Reduction of — (P) Steuart. From Galbraith	933
Briquettes of — for Reduction in Furnaces. (P) Rouse and Cohn	501
Iso-Artemisin. See under Artemisin.	
Iso-Hexanes. See under Hexanes.	
Isohyostigmine; Characteristics of — (Ogiu)	149
Iso-safrol; New Synthesis of — (Mameli)	41
Isostrychnine. (Bacovescu and Pictet)	1123
Italy; Alcohol Industry of — (T.R.)	53
Alcohol Taxation and Consumption in — (T.R.) ..	359
Olive Oil Imported by — (T.R.)	358
Spirit Taxation Law in — (T.R.)	1090
Sugar Production of — (T.R.)	1043
Tartaric Materials Exported from — (T.R.) ..	217
Ivory; Manufacture of Celluloid Paste in Imitation of — (P) Didier	355

Lead—*cont.*

Acetates; Preparation of —. (P) Heyl und Co. and Wulze	542
Carbonate; Preparation of —. (P) Heyl und Co. and Wulze	542
dithionate; Manufacture of —. (P) Betts	444
Ferrocyanide; Action of Oxalic Acid on —. (Leubner)	618
Hydroxide; Converting Lead Sulphate into —. (P) Ramage	546
Nitrate; Manufacture of Salts of —. (P) Mills	441
Oxide; Electrolytic Reduction of — for Use in Production of Nitrites. (P) Petit	1043
Oxides; Preparation of Active and Porous —. (P) Jacob	546
Oxides, Pulverulent; Manufacture of —. (P) Bertou	842
Peroxide; Electrolytic Preparation of —. (P) Steigelmann	1412
Silicofluoride; Manufacture of —. (P) Granger, From Mills	132, 132
and Silver Carbonates; Different Applications of Watt's Principle to Dissociation of the —. (Colson)	440
Sulphate; Conversion of — into Lead Hydroxide (P) Ramage	546
Lead-Potassium Sulphate; Existence of a Definite —. (Belton)	561
Leather; Apparatus for Manufacture of —. (P) Hall and Wright	449
Chrome; Application of Sulphide Colours in the Dyeing of —. (Epstein)	238
Chrome; Dyeing of — and Storing in the "Crust." (Lamb)	25
Cloths; Manufacture and Waterproofing of —. (P) Castle	36
Composition of Japanese —. (Paessler)	1075
Decoration of —. (P) Guetton-Dangon	617, 1170
Dyeing of —: (P) Abel. From The Actienges. für Anilinfabr.	842
(P) Rieder	968
Dyeing; New Processes for —. (Sedlacek)	130
Dyeing; Practical Difficulties in —. (Crockett)	439
Enamelled — and Manufacture of same. (P) American Patent Kid Co. From Adams, jun., and McKay	627
Formation of —. (Nierenstein)	899
Industry of Lyons in 1904. (T.R.)	1043
Manufacture of —: (P) Boulé. From Trencmann	98
(P) Owen and Threlfall	1245
(P) Zacharias	1245
Manufacture of Recovered — Printed in Sheets. (P) Soc. "Productos Químicos para la Agricultura e Industria."	1076
Manufacture and Waterproofing of —. (P) Castle	36
Preparation for Cleansing and Dyeing —. (P) Petersen	439
Producing Designs on both Sides of —. (P) Moore	1228
Sheep- with Chamois-like Finish. (Bum)	244
Sole; Quick Process of Tanning —. (Cladini)	387
"Soluble"; Detection and Determination of — in Tan-yard Liquors. (Parker and Casaburi)	871
as a Substitute for India-Rubber, &c. (P) Owen and Threlfall	1245
Tanning of Hides into —. (P) Tullis	744
Waterproofing Manufactured —. (P) Case	36
Leece; Production of Olive Oil in —. (T.R.)	865
Lecithin, Bromo-; Preparation of —. (P) Actienges. für Anilinfabr.	512
Preparations of — containing Iodine. (P) Rieder	512
Lemon Grass Oil. <i>See</i> Oils, Essential —. Leaves and Twigs; Oil of —. <i>See</i> Oils, Essential. Oil. <i>See</i> Oils, Essential.	
Lentiscum; U.S. Customs Decision on —. (T.R.)	161
Leucite; Disintegration of —. (P) Piva	845
Industrial Treatment of —. (P) Soc. Romana Solfati	926
Leucogalloyanine. <i>See</i> Dyestuffs.	
Lever Brothers' Soap Works; Visit to —	874
Levulose; Conversion of Dextrose into —. (Ost)	925
Determination of — simultaneously with Sucrose and Dextrose. (Lindet)	295
Identification of —. (Ost)	935
Influence of Inorganic Substances on the Rotation of —. (Rimbach and Weber)	515
Manufacture of —. (P) Stein and Loewenthal	1119
Preparation of Industrial — from Artichoke Roots. (P) Gallhat	144
Lichen Colours; Detection of —. (Tolman)	154
Lichens; Characteristic Constituents of —. (Hesse)	42
Light; Chemical Action of —. (Ciamician and Silber)	461, 641, 1326
Influence of — on Diazo Reactions. (Orton and others)	818
Lignite; Coking —, and Furnace therefor. (P) Hoernig and Mjøn	722
Lignocelluloses; Methoxyl Determinations in Certain —. (Wheeler)	748
Lime; Alkaline Reaction of Free — in Absolute Alcohol. (Drexel)	513
Analysis of Raw and Spent —. (Greville)	1126
Apparatus for Slaking —. (P) Tsuji	1108

Lime—*cont.*

Hydrated; Apparatus for Making —. (P) Quicklime. (P)	333
Hydrated; Manufacture of — from Oxide. (P) Reaney	28
Hydration of: (P) Ellis	1109
(P) Reaney	1230
(P) Thonin	1018
Hydraulic; Production and Application of Bags —. (Pasquay)	145
Kilns for Burning —. (P) Belmont and Middleton	92
and Lime-containing Slag; Slaking of —. (P) Ellis	1071
Manufacture of —. (P) Soc. Romane Foyer	117
Milk of —; Preparation of —. (P) Baul	332
Nitrate, Nitrite, or Sulpho-Nitrate of Nitrite of —. (P) Price	276
Sandstone; Composition of —. (P)	620
Treatment of —. (P) Ellis	277
Lime-sand Bricks; Effect of Iron Pyrites on the Method —. (Gerlugs)	621
Lime-sand Bricks; Influence of Added Lime Sand on the Mass for —. (Glasenapp)	732
Limestones; Determination of Magnesium and Calcium —. (Koppeschaar)	513
Determination of Silica in —. (Ashley)	45
Lime-Water and Milk of Lime; Production of —. (P) Paul	332
Limekiln; Construction of —: (P) Eldred Process Co. From Eldred	969
(P) Shoop	969
Linacrusta; Embossing and Colouring — and Apparatus therefor. (P) Walton	35
Linen Cloths and Yarns; Scouring, &c. —. (P) Adamson	330
Machine for Scouring —. (P) Thiebaud	194
Linnæ; Characteristics of —. (Hills and Wynne)	511
Linings for Centrifugal Separators. (P) Ohlsson	720
Linoleum; Apparatus for Printing —. (P) Shaw	274, 1180
Binding Medium for Securing —. (P) Suter	552
Linoleum; Manufacture of —: (P) Bremer-Linoleum-werke-Delmenhorst. From Gripp	98
(P) Bremer-Linoleum-werke-Delmenhorst. From Sesser	98
(P) Smith	682
Linoleum; Substitute for —: (P) Melville	1118
(P) Melville and Rees	1118
Linseed Oil. <i>See</i> Oils, Fatty.	
Lipase; Experiments on —. (Foote and Andrew)	945
<i>See also under</i> Enzyme Action.	
Liquids, Alcoholic; Fermentation and Clarification of —. (P) van de Kerckhove and Lebbe	146
Apparatus for Aerating Fermenting —. (P) Murphy	1183
Apparatus for Concentrating, &c. —. (P) Neumann and Stadel	321
Apparatus for Electrolysis of —. (P) Americus Electro-Thermite Co. From Dion	625
Apparatus for Elevating —. (P) Lowndes. From Hughes	124
Apparatus for Heating — by Electricity. (P) The Schoenberg Electric Appliance Co.	896
Apparatus for Purifying —: (P) Brooke	1215
(P) Howell	720
Apparatus for Raising —: (P) Giesserei und Maschinenfabr. Oggersheim Schütz	1162
(P) Hantke	428
(P) Palau and others	834
(P) Schwaninger	917
Apparatus for Separating — from Solids: (P) American Extractor Co. From Wheelwright	342
(P) Evans	501
Apparatus for Separating — from Vapours. (P) McNeil	792
Apparatus for Treating — with Gases or Vapours. (P) Defays	959
Apparatus for Treatment of — with Gases. (P) Quarez	235
Beaters for Mixing or Agitating —. (P) Reemer	663
Destroying Pathogenic Organisms in — and Apparatus therefor. (P) Griffith	811
Devices for Vaporising —. (P) Hayes	1293
Draw-off Cock for Viscous —. (P) Muller	321
Evaporation of —: (P) Lennox	1250
(P) Wallace and Speed	609
Evaporation, Concentration, &c., of —. (P) Montupet and Jannin	144
Extraction of — from Mineral, Vegetable and Animal Substances. (P) Inray. From Meister, Lucius and Brüning	281, 1072
Fractionating —. (P) Huglo	1295
and Gases; Apparatus for Effecting Exchange of Temperatures between —. (P) Christianson and others	720
of High Specific Gravity; Use of Alkali and Mercuric Iodides for —. (Dufloin)	988
Influence of Metals on Fermentation of —. (P) (Nathan)	745

1. <i>ing</i>	1216	Magnesium Alloys of — with Tin and Lead. (Kurnakow and Stepanow).....	972
2. <i>for Solat</i>	216	Amalgam: Action of — on Acetone. (Courturier and Meunier).....	344
3. <i>Mixtures</i>	262	Electrolytic Recovery of — (P) Becker Manufacturing Co.....	897
4. <i>Process for</i>	22	Production of Metallic — Electrically. (P) Morehead From Roberts.....	96
5. <i>Process for</i>	57	Magnesium Carbide: Existence of a — (Nance).....	545
6. <i>Purification</i>	62	Compounds: Organo-: Action of — on Phthalic Anhydride. (Bauer).....	213
7. <i>Rubber</i>	71	Carbonate: Determination of — in Limestones. (Koppeschaar).....	513
8. <i>Alloys</i>	77	Carbonate Trihydrate: Manufacture of — (P) Deutsche Solvay-Werke, A.G.....	1013
9. <i>Separation</i>	87	Chloride: Dehydration of — (P) Salzbergwerke, Neu-Stassfurt.....	1172
10. <i>Apparatus for</i>	133	Peroxide: Electric Production of — at Niagara Falls. (T.R.).....	947
11. <i>Apparatus for</i>	1055	Silicates: Research on — (Tischler).....	620
12. <i>Making</i>	1249	and Sodium Sulphates; Equilibrium between — (Denison).....	331
13. <i>of Bodies in</i>	1292	Magnetic Separating Apparatus. (P) Scholl.....	241
14. <i>and Filter</i>	791	Majolica: Definition of — Suggested. (Burt).....	133
15. <i>Devices for</i>	489	Maize: Albuminous Substance from — (P) Donard and Labbe.....	853
16. <i>and</i>	982	Maize Malt: Characteristics of — (Christek).....	285
17. <i>Station</i>	510	Oil. See Oils, Fatty.	
18. <i>sterilisation and</i>	39	Malachite Green. See Dyestuffs.	
19. <i>Lucius and</i>	1184	Malay States: Rubber Industry of the Federated — (T.R.).....	1043
20. <i>Treatment of</i>	685	Tin Exports of — in 1904. (T.R.).....	356
21. <i>Volatile. Apparatus for</i>	1053	Maletto (Mallet) Bark: Characteristics of — (Paessler).....	743
22. <i>Vapours of</i>	1248	Mallet Bark: a New Australian Tanning Material.....	743
23. <i>Liquors, Fermented: Material for Use in</i>	176	Malonyl- <i>p</i> -phenetidine: Manufacture of Dialkyl Derivatives of — (P) Abel. From the Actieniges. für Anilinfabr.....	1188
24. <i>Standards of Purity for</i>	934	Malt: Absolute Yield of Extract and Fine Grist Analysis of — (Bleich and Regensburger).....	286
25. <i>Litharg. Influence of</i>	945	Analysis of:.....	1129
26. <i>Lithium, Acid Oxalate of</i>	239	(Ehrlich).....	556
27. <i>Carbonate, Solubility of</i>	511	Determination of the Ash of — and Proportion of Sulphuric Acid in the Ash. (Windisch).....	155
28. <i>Crystals: Properties of</i>	1328	Determination of Yield of Extract in — (Bergdöhl Distillery: Application of Somlo's Process of Washing to — (Fröde).....	1038
29. <i>Lithographic Stone Trade of Bavaria. (T.R.)</i>	978	Extract in: Determination of — (Bleich and Regensburger).....	38
30. <i>Lithopones: Preparation of</i>	3	Food: Manufacture of — (P) Fränkel.....	640
31. <i>Liverpool Section: Chairman's Address to</i>	296	Grist from Different Mills. (Reinke).....	1319
32. <i>University, Extension of Laboratories of</i>	835	Grist: Heat Evolved on Wetting — (Hoffmann and Philippe).....	980
33. <i>Liverworts, Oils of the. See Oils, Essential.</i>	442	Increasing the Brewery Yield of Extract from — (Merz).....	204
34. <i>Lixivating Apparatus:</i>	1089	Influence of Duration of Germination on Nitrogenous Constituents of — (Kukla).....	1024
35. <i>(P) Linze</i>	670	Maize —: Characteristics of. (Christek).....	980
36. <i>(P) Sanerbreij</i>	686	Preparation of — in a Vacuum. (P) Wettig.....	285
37. <i>Locomotives: Factory Act Regulations for</i>	800	Production of — (P) Rice.....	557
38. <i>and Waggon: Use of — on Lines and Sidings in</i>	794	Proteolytic Enzyme in Bavarian — (Krandauer).....	1318
39. <i>Logwood Black suitable for Printing on Tissues prepared</i>	552	Red Unleaded — (Will).....	852
40. <i>with Naphthol. (Wicktoroff)</i>	1008	Sulphuring — so as to avoid Contaminating with Arsenic. (P) Baker and Ling.....	286
41. <i>EXTRACTS FROM HAYTI. (T.R.)</i>	432	See also Barley.	746
42. <i>EXTRACTS, Increasing the Tinctorial Yield of</i>	1191	Malts: Albumin and Extract Percentages of Season 1904-5 (Neumann).....	286
43. <i>Lubricant which forms Stable Emulsions with Water. (P) Orbanek</i>	552	for Different Beers: Requisites of — (O'Connor).....	144
44. <i>Lubricants: Apparatus for Purifying Thick</i>	315	Malting of Amylaceous Materials. (P) Effront.....	206
45. <i>Kettler</i>	820	Apparatus for — (P) Krueger.....	146
46. <i>Composition of</i>	694	Process and Apparatus for — (P) Berliner Act. Ges. für Eisengiess u. Maschinenfabr.....	1318
47. <i>(P) Henniquin and Cayeux</i>	123	Maltose: Detection and Determination of — in Presence of Dextrose. (Baker and Dick).....	352
48. <i>Examination of</i>	343	and Isomaltose: Synthesis of — (Armstrong).....	1246
49. <i>Manufacture of</i>	198	Methylation of — (Purdie and Irvine).....	906
50. <i>Valuation of — with special Reference to Cylinder</i>	35	New Colour Reaction for — (Wöhlk).....	47
51. <i>Oils. (Richardson and Hanson)</i>	832	Quantitative Hydrolysis of — (Pfyf and Linne).....	935
52. <i>Lumber: U.S. Customs Decision on Fireproofed</i>	1024	Maltoxydase: Characteristics of — (Issajew).....	1024
53. <i>Luminous Composition. (P) Kunz</i>	873	Manchester Corporation Sewage Works: Visit to — Ship Canal: Visit to —.....	873
54. <i>Lyes: Earthenware Cocks for Use with</i>	1178	Mandarin Oil. See Oils, Essential.	
55. <i>Sulphate Cellulose —: Utilisation of. (Ahrens)</i>	46	Manganese as an Anode. (Müller).....	1178
56. <i>Lyons. See under France.</i>	1085	in Cyanide Solutions: Colorimetric Detection and Determination of — (Clenell).....	46
		Determination of — in Presence of Chromium. (Gröger).....	1085
		Effect of — in Low-Silicon Cast-Iron. (Loudenbeck).....	735
		Testing Zinc Oxide for Determination of — (de Koninck).....	152
		Manganese-Steel Rails or Shapes: Manufacture of — (P) Hadfield.....	737
		Manganese Boride: A New — (du Jassonneix).....	94
		Borides: Preparation and Properties of — (Wedekind).....	440
		Chromates. (Gröger).....	545
		Determination of — as the Green Sulphide. (Olsen, Clowes and Weldmann).....	106

	PAGE		PAGE
Manganese— <i>cont.</i>		Matte; Converter for —; Smelting —. (P) Gale	929
Resinate; U.S. Customs Decision on —. (T.R.)	1	Converting — (P) Bagg	929
Silicide; Preparation of —. (Vigouroux)	1	(P) Barr	242
as Sulphide; Determination of — in Ores containing Barium. (Blum)		and Slag from — (P) Harris	804
Sulphides; Composition of the Four —. (Olsen and Rapalle)		Mazut; Ascertaining — and Quality of Lubricant (Charitschkow)	81
Mangrove Bark from Angola. (T.R.)		See also Mazut.	
Bark Industry of Mozambique. (T.R.)	144	Measuring Apparatus; —. (P) Siemens & Co.	77
Bark; Utilisation of — in Queensland	144	From Siemens and Halske	77
Mantle; Incandescence Self-lighting —. (P) Ronxville and Michaux	612	Meat Extract; Determination of — Organically Combined Phosphorus in — (Sever and Singewald)	124
Theory of the Incandescent —. (Lewes)	124	Extracts; Preparation of —. (P) Giantar and Ross	557
Incandescence; Classification of — in Russian Tariff. (T.R.)	355	Powder or Meal; Preparation of —. (P) Murray	685
Incandescence; Incandescing Media for —. (P) Langhans	1007	From Maragliano	685
Incandescence — and Making same. (P) Reeser	1218	Preservative; Dangerous —. (P) Craven	949
Incandescence; Manufacture of —:		Preserving —. (P) Craven	452
(P) Comp. Franc. de l'Acétylène Dissons	962	Meconic Acid and Meconates in the — of Opium. (Mallinckrodt and Dunlap)	938
(P) Crossley	429	Medicines; Manufacture of — from —. (P) Gross	209
(P) de Valeriola and others	793	Gross	209
(P) Moeller and others	431	Meeting; Proceedings of the Twenty-fourth Annual	715
(P) Saubermann	722		871

Manure, Artificial; Manufacture of —. (P) Wardle	36	of Refractory Ceramic Products; Determination of —. (Hercus)	133
or Fertilisers, Artificial; Manufacture of —. (P) Hammerschlag	203	Menthol; Synthesis of —. (Haller and Martine)	248
Manufacture of a —. (P) Soc. Aktieselskabet det Norske Kvaeststoffkompagni	1315	Thymo- and its Derivatives. (Brunel)	248
Manufacture of — from Calcium Humate. (P) Bourgeois de Mercey	1076	Menthone derived from Hexahydrothymol. (Brunel)	455
Manufacture of — from Oilal. (P) Bollé. From Schmidt and Co.	979	Synthesis of —. (Haller and Martine)	248
New Humous —. (P) Jeannin	1245	Mercurising Apparatus:	
Waste Sulphite Cellulose Lyes as —. (Ahrens)	343	(P) Butterworth and Sons	495
Manures; Manufacture of —. (P) Bontan	900	(P) Crompton and Horrocks	616
Manufacture of Humous —. (P) Bontan	979	(P) Edlich	274
Retrospection of the Soluble Phosphates in Mixed —. (Gray)	935	(P) Mather, Hübner and Pope	1225
See also Fertilisers.		Apparatus and Process. (P) Mather and others	272
Maple Products; Detection of Cane Sugar in —. (Woodman)	1191	Process. (P) Mather, Hübner and Pope	1226
Marble, Artificial; Manufacture of —:		Studies on —. (Beltzer)	965
(P) Lefranc	443, 1173	Mercuric Acetate; Action of Aldehydes and Acetone on —. (Lasserre)	1028
(P) Thom	892	Acetate in Solution in Glacial Acetic Acid; Reactions of certain Substances with —. (Leys)	558
Artificial; Production of Objects of —. (P) Hülberg	621	Chloride Solutions; Action of Acetylene on —. (Hofmann)	48
Completely Colouring —. (P) Fabr. Brand and Co.	892	Chloride; Volatility of — in Aqueous Solution. (Minozzi)	154
Producing Grain in —. (P) Fabr. Brand and Co.	892	Iodide; Action of — on Sulphuric Acid and on the Mercuric Sulphates. (Ditte)	618
Marc of Olives; Apparatus for Distillation of Exhausted —. (P) Bernard	540	Oxalate (Eder's Solution); Photochemical Behaviour of —. (Jodlbauer and von Tappeiner)	903
Marl; Apparatus for Treatment of —. (P) Wilkes	848	Oxide; Compound of — with Antipyrine. (Astre and Ville)	856
Marseilles. See France.		Zinc Cyanide. (Dott)	902
Mascarenhasia; Characteristics of —	35	Mercury; Apparatus for Distillation of —. (Pollak)	243
Mash; Separating By-Products of Fermentation from —. (P) Pampe	1025	British Trade in — in 1904. (T.R.)	112
Tun; Internal Rakes in the —. (Lewis)	246	in Ores, &c.; Volumetric and Gasometric Determination of —. (Ebler)	1257
Mashes, Potato; Regulating the Speed of Fermentation of —. (Christel)	206	in Organic Compounds; Determination of —. (Rupp and Nöll)	350
Mash-Residues; Extraction of —. (P) Prandtl	557	Production of Toseany. (T.R.)	567
Mashing Apparatus and Filter for Liquids. (P) Selg	100	Production of — in the United States. (T.R.)	160
Influence of Gypsum on Starch, and Albumin Conversion in —. (Windisch & Boden)	99	Production of the World. (T.R.)	464
Masseuite; Apparatus for Filtering and Washing —. (P) Roy	285	Use of Aluminium for Detection of —. (Tarugi)	334
Preparation of —. (P) Roy	507	Volumetric Determination of —. (Rupp)	752
Recovery of Sugar from —. (P) Huch	450	Mercury Compounds for Medicinal, Disinfecting and Antiseptic Purposes. (P) Cooke	1250
Treatment of — and Apparatus therefor. (P) Roy	1315	Compounds; Photographic Radiation of some —. (Fleming-Struthers and Marsh)	295
Masseuites; Apparatus for Boiling —. (P) Roy	1077	Formates; Examination of —. (Varet)	812
Apparatus for Cleansing —. (P) Landrin and Moulrier	745	Oxyhalides; New —. (Fischer and von Wartenburg)	454
Mixing Device for —. (P) Soc. Anon. de Constructions Mécaniques de St. Quentin	745	Preparations; Production of Easily-Soluble —. (P) Emmel	747
Preparation of — continuously. (P) Roy	1024	Salts; Explosive —. (Hofmann)	690
Process and Apparatus for Boiling —. (P) Roy	980	Salts (Mercury Cholate); Preparation of —. (P) Wetter. From Riedel Aktienges.	939
Mazut; Use of — for Fuel in Iron and Steel Works. (Heck)	22	Salts; Photographic Emulsions of —. (Castellani)	750
See also Mazut.		Succinimide; Reactions of —. (Rupp and Nöll)	350
Matches; Composition for —. (P) Staier	152	Vapour Arc; Conducting Chem. Reactions by means of a —. (P) Carolan. From The General Electric Co.	503
Igniting Composition for —. (P) Chem. Fabr. Griesheim-Elektron. From Dieffenbach and Marburg	903	Pump; Automatic —. (Ubbelohde)	1085
Igniting Compositions for; Analysis of —. (Bender)	1257	Pump; Rotating —. (Kaufmann)	1085
Ignition Material for — free from Phosphorus. (P) Gans	457	Metal, Alkali; Recovery of — from Alkali Metal Amalgam. (P) Baker and Burwell	282
Inflammable Paste for —. (P) Bokmayer and Swoboda	1256	Electrolytic Deposition of —. (P) Hoopes	531
Manufacture of —. (P) Christensen	513	Electrolytic Deposition of — on Non-metallic Bodies. (P) Blackledge	1073
Manufacture of Wax —. (P) Bals	1324	Engraving and Etching —. (P) Dejeu	975
Paste free from White Phosphorus for Manufacture of —. (P) Barbé	1085	Incorporation with another Metal without Fusion. (P) Herrenschildt	1310
Sulphur Compounds and Priming Compositions for Manufacture of —. (P) Wetter. From Riedel	291	Metallic Deposits on; Production of —. (P) Lévy	625
Match-Sticks; Manufacture of — from Fir and Pine Wood. (P) Falck	1325	Mixtures Produced in Electrolytic Metal Refining; Treatment of the —. (P) Belts	626

Formation of Alkaloids in —. (Pictet)	856
Nutrient for — and Insect Destroyer. (P) Jenkner and Pleyl	101
Preparing Dried — for Bleaching and Dyeing. (P) Seibt und Berker	671, 1011
Plaster, Artificial; Manufacture of —. (P) Elmes.....	674
Calcining —, and Apparatus therefor. (P) Adolph Leitelt Iron Works. From Simonds	240
for Cast Plaster Floors; Improvement of —. (P) Heintzel and Cramer	674
Compounds; Making Ingredients for —. (P) Hirt	1173
Hardened; Manufacture of —. (P) de Werra	972
Manufacture of Articles by Agglomeration of —. (P) Pampy	490
Manufacture of — from Spent Gas Lime. (P) Berry	1110
Treating Gypsum to Obtain either Slow- or Quick-Setting —. (P) Perin	499
Relation between Solubility of Calcium Sulphate and Hydration of —. (Rohland)	333
Utilisation of Over-burned —. (P) Heintzel and Cramer	674
Plaster-of-Paris; Manufacture of —, and Apparatus therefor. (P) Brothers	443
See also Calcium Sulphate and Gypsum.	
Plastic Compositions:	
(P) Collardon	842
(P) Grote and Perry	198
(P) Elmes	674
Material from Nitrocellulose. (P) Béthisy and Soc. Rose et Cie	344
Substances from Cellulose of Gorse, &c. (P) Hotteloup	344
Plates, Photographic —. See under Photographic.	
Platinum Contact Substances; Revivification of —. (P) Badische Anilin und Soda Fabr. From Knietseh and Scharif	240
Determination of —. (Nordenskjöld)	1127
Electrolytic Solution of —. (Ruer)	291, 1114
Electrolytic Solution of —, in Sulphuric Acid. (Brochet and Petit)	336
Metals; Determination of the —. (Nordenskjöld)	1033
Production of — in Russia. (T.R.)	567, 821
Production of — in the United States. (T.R.).....	160
Separation of — from Iridium. (Quennessen).....	904
Withdrawal of Oxygen by —:	
(Lucas)	441
(Magnus)	193
Platinum Chloride; U.S. Customs Decision on —. (T.R.)	1044
in Colloidal Form; Preparations containing —. (P) Kalle und Co.	813
Plumbago; Manufacture of Stratified Blocks of —. (P) Morgan Crucible Co. and Speirs	805
See also Graphite.	
Poisoning by Metallic Compounds; Soap Preparation for Preventing —. (P) Nusch. From Chem. Werke Ges. vorm. C. Zerbe	283

Pulverulent Materials; Converting — into Lumps. (P)	720
Pohl	720
Pumice; Agglomeration of —. (P) Soc. Geoffroy, Jaquet et Guillemin	734
Pump; Automatic Mercury —. (J. Bickelside)	1085
Rotating Mercury —. (Kaufmann)	1085
Two Modifications of the Töpler —. (Stöck)	844
Puzziolana; Manufacture of —. (P) Soc. Anon. Romain Boyer	1173
Pyramidone and Antipyrine; Volumetric Determination of — in a Mixture of the Two Substances. (Pégurier)	1250
(Dimethylaminoantipyrine); Determination of —. (Pégurier)	1250
Pyrazole, Phenylmethylamidochloro-; Manufacture of —. (P) Meister, Lucius and Brüning	44
Pyridine; Action of Formaldehyde on —. (Formanek)	314
Manufacture and Recovery of —. (P) Lessing and Wilton	1200
Mercuriodides. (François)	455
Purification of —. (Barthe)	722
Solutions; Reactions of Salts in —. (Naumann)	36
U.S. Customs Decision on —. (T.R.)	215
Pyrimidine Derivatives; Manufacture of —. (P) Newton. From Bayer and Co.	512
Derivatives, Thio-; Preparation of —. (P) Bayer and Co.	156
Diminothio-, and its C-C-Dialkyl Substitution Products; Preparation of —. (P) Bayer and Co.	814
Production of Cyano-derivatives of —. (P) Maison E. Merck	151
Pyrimidines, 2-Alkyl-; Preparation of —. (P) Bayer and Co.	456
C-C-Dialkyl-2,4-Diimino-6-Oxy-; Preparation of —. (P) Merck	1255
4,5-Diamino-2,6-dioxy-; Preparation of —. (P) Merck	1030
Preparation of —. (P) Merck	689
Production of Cyclic —. (P) Merck	689
Pyrites; Apparatus for Treating —. (P) Simons	90
Burnt; Briquetting of —. (P) Baldens	624
Sulphur in; Determination of —. (von Knorre)	106
Sulphur in; Determination of — by Lunge's Method. (Pattinson)	7
in the United States. (Schnatzenbeck). (T.R.)	158
Pyritic Smelting; Amount of Air Required in —. (Wright)	756
Pyrocatechuic Monoalkyl Ethers; Compounds of —. (P) Fehrlin	345
Pyrometers: (P) Barnes and Tory	320
(P) Féry and others	210
Pyrometry; Optical —. (Waidner and Burgess)	320
Pyrene Dyestuffs. See Dyestuffs.	
Pyroxylin; Manufacture of Films, Sheets or Masses of — (P) Abel. From Acétienges. für Anilinfabr.	248
Materials; Printing on —. (P) The Whitehead and Hoag Co. From Roehm	728
Pyrrhotite; Separation of — from Chalcopyrite and Gangue. (P) Judson	1177
Pyrrrol Blue. See Dyestuffs.	
Pyruvic Acid; Colour Reaction for Determination of —. (Alvarez)	817

Q

Quarries; Report on — for 1903. (T.R.)	863
Quebracho Chips; U.S. Customs Decision on —. (T.R.)	217
Exports of — from Argentina. (T.R.)	757
Tannin. (Nierenstein)	907
Queensland. See Australia.	
Quercetol Isomeride. See Dyestuffs.	
Quicklime in a Mixture of Sand and Lime; Apparatus for Slaking — with Steam. (P) Krefé	241
Quinazoline Derivatives; Preparation of —. (P) Gabriel and Colman	1031
Quinine Acid Hydrochloride. (Garsel)	902
Formates; Preparation of —. (Lacroix)	902
Hydrochloride; Neutral —; (Carette)	1081
(Erba)	208
Italian State —. (T.R.)	1331
Java —. (T.R.)	1135
Preparations and Salts; U.S. Customs Decision on —. (T.R.)	255
Prices of Javan —. (T.R.)	758
Reaction for Distinguishing — from Cinchonine. (Reichard)	562
Salts. (Guigues)	1081
Salts; U.S. Customs Decision on —. (T.R.)	359
Solubility of — in Ammonia. (Duncan)	460
Sulphate; Testing of —. (Duncan)	460

Quinizarin. See Dyestuffs.	
Quinol, Hydroxy-; —. Dyestuffs.	
Quinoline Dyestuffs. —. Dyestuffs.	
Quinone Imides. —. Dyestuffs.	
Quinophthalone. See Dyestuffs.

Wines; Ageing of ——— (Malvesin)	1024
Artificial Ageing of ——— (P) Pozzi-Escot	1121
Continuous Direct Rectification of ——— (P) Baudry	1079
Continuous Rectification of ——— (P) Baudry	1080
Fermentation of ——— (P) Vignier	287
Fortification of Poor ——— (P) Francon	341
Liquor; Determination of Glycerol in ——— (Rocques)	1038
Maturing of ———, and Sterilising Liquids. (P) Dorn	684
Objectionable Method of Fining ——— (Bodmer)	937
Reduction of Amount of Sulphurous Acid in White ——— (Carles)	38
Wire; Galvanising ——— Electrolytically. (P) American Steel and Wire Co. From Meaker	1073
Galvanising, Tinning and Plating ——— (P) Goodson	550
Iron; Hardening of ——— (P) Krantschneider	678
Wires; Electrolytic Production of Fine Metallic ——— (Abraham)	679
Withnell Powder; Composition of ———	986
Wollastonite; Separation of Graphite from ——— (P) Kron	197
Wood; Apparatus for Carbonising ——— (P) Hammer	828
Apparatus for Distillation of ———; (P) Dungan	271
(P) Fiveash	613
(P) Harper	613
(P) Williams	1058
Apparatus for Impregnating and Staining ——— (P) Kron	241
Artificial; Manufacture of ——— (P) Gutzeit	500
Apparatus for Recovering Turpentine, &c. from ——— (P) Sibbitt and McLean	807
Carbonising ———, and Apparatus therefor. (P) Müller	839
Cellulose; Conversion of ——— into Sugar. (P) Even and Tomlinson)	868
Cellulose Xanthate a Substitute for ——— (P) Soc. Franç. de la Viscose	855
Colouring of ——— (P) Kormann	1004
Distillation Industry, The ——— (Muspratt)	372, 473
Fireproofing of ——— (P) Blenio	136
Fireproofing Compound for ——— (P) Patten	1173
Grinding ——— for Manufacture of Paper. (P) Wele	40
Heating, Steaming, and Chemically Treating ——— (P) McWhirter	443
Impregnation of ——— (P) Hulsberg and Co.	278
Impregnation of ——— with Antiseptics, and Apparatus therefor. (P) Conti-Vecchi	278
Impregnation of ———, and Apparatus therefor. (P) Electric Timber-Seasoning and Preservation Co. and West	92
Impregnation of ——— Uniformly. (P) Heise	500
Liquid for Impregnation of ——— (P) Wolman	971

Y

Z

ne—cont.

Crystallisation of — by Electrolysing its Salts. (Sapozhnikow)	800
Determination of — (Spitzer)	111
Electro-deposition of — (P) Kendall	319
Electrolytic Determination of — for Technical Pur- poses. (Jene)	74
Electrolytic Extraction of — from its Ores. (P) Betts	8
Electrolytic Recovery of — (P) Decker Manufac- turing Co.	1113
Extraction of — (P) de Laval	738
Extraction and Purification of — (P) Cunningham	1113
Furnaces for — (P) Armstrong	1278
in Light Zinc-Aluminium Alloys, Determination of — (Seligman and Willott)	228
Methods for Separating and Determining — in Blends, &c. (Pattinson and Redpath)	445
Muffle for Distillation of — (P) Unger	148
Obtainment of — from its Ores (P) Peacock	975
Precipitation of — from Liquids (P) Havemann	159
Production and Market Position of — during 1895- 1905. (T.R.) Krull	1208
Properties of Sheet — and Influence of Impurities. (Meyer)	894
Recovery of — from Ores. (P) Stewart	33
Separation of — Electrolytically, from Zinc Chloride in Acetone Solution (Patten)	1191
Separation of — from Iron, by Ammonia. (Funk)	358
Sheets, Nickel-Plated; U.S. Customs Decision on — (T.R.)	1019
Zinc Blende; Separation of — from Ores, &c., by Flota- tion of — (P) de Bavay	129
Blende; Treatment of — (P) Simm and others	40
Borate or Oxyborate; Preparation of — (Holder- mann)	275
Carbonate; Action of Alkali Chlorides on — (Pas- samanik)	

Zinc—cont.

Carbonate, De-termination of — by — (P) Lances	925
in Presence of — (Canton & J)	
Carbonate; Manufacture and Application. (P) Barber	35
Cement for Steels. (Lavache)	742
Chloride; Obtainment of — (P) Wikand	732
Chloride Solutions; Treatment of — (P) H	197
Chloride Solutions; Volatilizing Decomposition (P) Carstangen	
Compounds; Electro-Process of Separation "Ferriferous"	
Wire Co. From Molten — American Steel	
Hydroxide, Direct Production of — (P) Lances	
Hydroxide; Obtaining — the Wet Way. (P)	845
Lance	1311
Oxide; Extraction of — (P) Lances	890
Oxide; Method of Making Polishes — Silicates Applied to — (Dubois)	152
Oxide for Quantitative Determination of — Manganese; Testing of — (de Koninck)	947
Peroxide; Electric Production of — (P) Lances	139
(T.R.)	1013
Substances containing; Treatment of — (P) Simm	239
and others	93
Sulphate; Apparatus for Manufacture of — (P)	148
de Stucklé	42
Sulphate; Decomposition and Formation of —	
Heating and Roasting. (Hofman)	
Sulphide; Apparatus for Recovering — (P)	
Sulphide; Apparatus for Recovering — from —	
(P) Gillies	
Sulphide; Manufacture of — (P) Marlier	
Zinc-Antimony Alloys. See under Alloys.	
Zirconium Oxychloride (Detection of Zirconium). (Ruert)	1028
Zirconosulphuric Acids. (Ruert and Levin)	246
Zymase, and Alcoholic Fermentation. (Harden)

*Meeting held at the University, Liverpool, on Wednesday,
 30th November, 1904.*

MR. EUSTACE CAREY IN THE CHAIR.

CHAIRMAN'S ADDRESS.

CHEMICAL INDUSTRIES OF THE UNITED STATES.

You will naturally expect that I shall have a great deal to say about what was to be seen in the United States during our recent memorable visit, a visit that was made most pleasant to all the members of the Society who took part in it. We all have, and shall always retain, a very lively recollection of the great hospitality with which we were received, and the unvarying kindness which was shewn to us by the office-bearers and by many of the members of the New York and other American Sections. I cannot speak too highly of their generous treatment of us, and of the immense labour which they must have bestowed upon the preparation and the carrying out of their plans for our benefit.

Of course, in a visit of this kind, we were not by any means exclusively occupied in studying technical processes. Our hosts were naturally desirous of showing us and we were naturally desirous of seeing their country and their institutions, and in the few remarks which I shall venture to make to you this evening, I shall not confine myself to an account of technical matters, but shall endeavour also to touch upon some subjects of general interest. But I must confine myself to matters which were brought under my own notice, and not attempt to give anything like a general account of the whole of the proceedings.

In fact, I may say here, that if there is one thing more than another in which the Americans appear to be interested, it is in the subject of education. Their Universities are numerous. Their professors are strongly alive to modern requirements, and thoroughly up-to-date in their methods; in fact, more than one University is attracting students from Europe and from all parts of the civilised world. I don't mean to affirm that education is all that the American citizen cares for, for it goes without saying that he has a great appreciation of the almighty dollar, but the accumulation of a pile does not satisfy even their millionaires, who love their country, labour almost night and day to develop its resources, and are keenly alive to educational requirements, and give like princes to educational establishments, in order that their young men and young women may be well equipped for the struggle of life. This feeling is not only that of the well-to-do, but it is shared by the working people, who are eager to take advantage of any schools within their reach, and they have one immense advantage over the majority of people in this country—that if poor they are not ashamed to be poor, they are not ashamed to take any opportunity of earning their living and improving their position at occupations which many of our young students would despise. In this connection

I may mention the case of a young man with whom I came in contact at the St. Louis Exposition. He was a Canadian (and I may here say, that my remarks apply to Canada as well as to the United States), and during his summer vacation he was presiding over a cigar stall, selling cigars for a living, with the expectation of putting a little money by to help him in his university career in the winter. This kind of thing has been done in Scotland, we know, but one does not see many such cases in England. Americans often boast that their land is the land of freedom. It is so in some respects, and especially so in the freedom with which the poor mingle with the well-to-do and well educated on terms of apparently perfect equality. In short, I may sum up the situation by saying that the celebrated and all-powerful Mrs. Grundy has but little influence in America.

In connection with education I may mention the wonderful library at Washington. The building is stated to have cost \$6,343,000, the land on which the building stands \$585,000. At the present time there are over 40 miles of bookshelves filled, and there is provision made for extension up to 150 miles of bookshelves. The reading room is large, and the mechanical arrangements are very complete for carrying the books from the shelves to the reading room and back from the reading room to the shelves. The reading room is open on Sundays from 2 to 10, and my informant told me that it was always well filled, in fact, he said every seat was taken, people waiting to come in some time before it was opened. There are 300 officials connected with the working of the library. The decoration of the building is extremely beautiful and artistic, and indicates the delight with which the American people have erected and are maintaining that building in the interest of education.

At New York we had a very considerable list of works to visit, viz.:—The Nichols Chemical Co., the New York Edison Co., Westinghouse, Church, Kerr and Co.'s Power-House for the Pennsylvania R.R., the Ravenswood Works of the Consolidated Gas Co. of New York, New Jersey Zinc Co., the Balbach Smelting and Refining Co., the Murphy Varnish Co., George Elmer's Brewery, Carl Schultz Mineral Water Factory, paint works of the F. W. Devoe and C. T. Reynolds Co., and of J. W. Masury and Sons.

This list gives an idea of what was provided for us, more or less, in all the cities we visited. It was impossible for any one individual to visit a quarter of the works that were open for inspection, therefore individual members notified the particular works to which they wished to go.

In addition to the works, of course there were places of interest in New York and the neighbourhood—such as the Columbia University, Metropolitan Museum of Art, American Museum of Natural History, and special collections of jade, porcelain and jewellery.

Personally, I was only able to visit the New York Edison Co., Westinghouse, Church, Kerr and Co.'s Power House, and the Ravenswood Works of the Consolidated Gas Co.

The Edison works is an enormous and impressive place. They use 200,000 h.p., and claim to obtain 1 i.h.p. per 12½ lbs. of dry steam.

At the works of the Consolidated Gas Co., the boiler fuel gases we were told contain 14 per cent. of carbon dioxide, and the gases leave the boilers at a temperature of only 400° F.; from 8 to 8½ lbs. of water are evaporated per lb. of fuel. They use anthracite smalls with no dust, what they call "corn size" as received from the colliery. I was very much struck by the uniformity of the coal delivered to the various works. The collieries in the United States separate their coal into various sizes to meet customers, all sizes without smalls. I was told that they used up their small or dust in coke ovens. They make various sizes of coal, some the size of walnuts, some larger, but all beautifully clean and free from dust. With absolute uniformity of size, it is of course easier to fire with regularity and obtain uniform results.

The Westinghouse Works at Pittsburg are most interesting. At the time of our visit they were very busy in steam turbines, and had hardly any orders for large steam engines. They make turbines up to 3000 h.p., and work them with a vacuum of 27.28 inches of mercury,

They informed us that the turbine has an advantage over the steam engine in that it can work at 30 to 40 per cent overload or under load with the same economy of steam, whereas steam engines must run at about the power for which they are constructed, or their valves are set.

Many hundreds of women and men are employed in winding the dynamos, an operation over which great care is taken. In fact, I was told by the manager of a works that he suffered from the floods last spring that he lost several of the Westinghouse motors under water for a considerable time, but that they were so well wound that, even as they were dry, they worked as well as new. The care also that they took with the balancing of the armatures is well repaid by the steady, smooth working of their dynamos. The Westinghouse firm were constructing a dynamo for the Manhattan R.R., 5000 h.p., with a fly-wheel weighing 100 tons or over; in fact, the machines are so large that the machine tools for planing, drilling and so on have to be moved to the work, and not the work to the machine tools. Large tracts of floor are laid with thick plates planed a dead level, so that a piece of plant can be fastened down to any part of the surface, and then and there it is level, and a machine tool can be brought to it and can operate upon it without delay.

Perhaps the most striking sight that we saw at Pittsburg was the Homestead Works of the Carnegie Steel Co. The smelting works are on one side of the river, and the rolling mills on the other. We visited the rolling mills. The liquid cast-iron from the smelters is conveyed in fire-clay lined ladles of very large size in trucks from the iron works over a bridge to the rolling mills, taking about 45 minutes for the journey. The iron, however, is in such a large mass that it will remain liquid for four hours, and the cooling during the 45 minutes' transit is no hindrance to the subsequent operations of bessemerising puddling, and rolling.

We began at an open hearth from which a "bloom," about 5 to 6 feet long, about 4 feet wide, and about 15 inches thick, was taken, and run backwards and forwards through several sets of rolls, until it became a thin sheet of about 45 or 50 feet long. All this was done before the heat acquired in the smelting furnace has disappeared.

Water was thrown in plenty on the rolls, but the heat continued sufficient until the iron was rolled to its required size and shape. The water thrown upon the rolls, of course, to a great extent, fell upon the iron which was passing through the rolls on which it ran about in a spheroidal condition. The men by the side of the rolls frequently spread a shovel or two of coarse salt over the iron close to the rolls, when the pellicles of gas interposed between the spheroids of water and the iron were broken, and the water brought into direct contact with the iron, causing a series of deafening explosions. This perpetually recurring noise, coupled with the noise and rattle of the rolling mills themselves, rendered it almost impossible to ask an audible question or to hear a reply—conversation was, therefore, difficult.

There were several sets of rolls occupying more than 100 feet each of the shed, some for sheets, some for rods, some for girders, &c. In some cases a mass of iron has to go through two or more separate machines. These machines work together like clockwork. Not an instant seems to be lost. In fact, the machines work together with the precision of soldiers at parade. The men who drive these enormous machines seem to have no respite. They work two shifts in the 24 hours in dust, great heat, and overpowering noise. They earn from \$4 to \$5 a day.

The Homestead Works were fully employed, but we were given to understand that some of the other works belonging to the Company were not working full; but their policy is to work those works full which work most cheaply, and, as the Homestead Works is one of their cheapest, they naturally continue it in full operation. The excellent organisation of the labour in this works, the extent to which power is used, and the supreme effort all concerned in those rolling mills have to make in order to avoid the loss of a moment of time, is the great secret of their success. Labour, as everyone knows, is expensive, power is comparatively cheap, and the intelligent manage-

ment of labour-saving contrivances all through the United States is the one thing needful for success, and that one thing being of prime and ever present necessity, accounts for the extraordinary extent to which brain-work in connection with the management of large industrial processes has been cultivated, more perhaps than in any other manufacturing country in the world.

I saw the same kind of organisation in a large zinc-smelting and zinc-rolling works near Chicago. The men who have the responsibility of rolling the zinc receive up to \$6 a day of eight hours, but they are kept at work in such a way by subsidiary appliances for the furnishing with due speed and punctuality of the material to be rolled, that the sheets of zinc appeared to follow one another through the rolls almost as quickly as you could turn over the pages of a book. At this works they had a most beautiful quality of zinc blende to treat; their colliery formed a part of the premises, and the coal at the pit mouth was not farther from the furnaces than the receiving siding is from the furnaces in an ordinary English works, and far less distant than in many with which we are familiar. Coal costs them 90 cents for run of mine.

I have a few words now to say about St. Louis and the wonderful "Louisiana Purchase Exposition," as it is called.

An American historian says "that the annexation of Louisiana was an event which gave a new phase to politics, and ranks in historical importance next to the Declaration of Independence and the adoption of the Constitution." The Exhibition is intended to commemorate the centenary of this great event. For many years the region of the Mississippi valley was coveted by both Great Britain and France, and in 1801 there was great fear that the army of 40,000 sent by Napoleon Bonaparte to suppress the insurrection in San Domingo was really intended to take military possession of Louisiana and the Floridas. Fortunately, Napoleon's attention was, of necessity, taken up with European complications, and a peaceful termination of a very critical situation was effected by Mr. Jefferson when he took office as President in 1801, and the treaty for the transfer was concluded on April 30, 1803, by Napoleon and by Thomas Jefferson, author of the "Declaration of Independence," and third President of the United States. The American people have thought it desirable to celebrate this very important event, and they have celebrated it in a right royal manner. The great area covered by the Exhibition was 1240 acres; the Chicago Exhibition covered 633 acres; the Paris Exhibition in 1900 covered 336 acres; the Buffalo Exhibition 300 acres; and the Centenary Exhibition at Philadelphia 236 acres.

In the St. Louis Exhibition 128 acres were covered by the various buildings required for the Exhibition, and this Exhibition is remarkable also in the fact that no charge was made to exhibitors for space or power.

The amount of money spent by some exhibitors was no doubt very great. Platt Bros., of Oldham, had a very fine exhibit of their cotton machinery, the Westinghouse firm also of theirs, and one of their people told me that their exhibit had cost them £40,000. They had the contract for supplying power to the Exhibition.

The great buildings, although temporary and made of lath and plaster, were most artistically designed, and were as beautiful in proportion, in outline, and in detail as if they had been built to last for centuries. In fact, the design and decoration of the outside of these buildings must have cost the architect or architects as much time and study as if the buildings were required to be permanent.

I am glad to be able to say, and I am sure those members of the Society who saw the Exhibition will agree with me, that the British Chemical exhibit was, thanks to the sub-committee of the Royal Commission for the St. Louis Exhibition, consisting of Dr. Boverton Redwood (Chairman), Mr. Thomas Tyrer, Mr. Gordon Salamon and Mr. Wightman, acknowledged by all to be an excellent exhibit and worthy of British enterprise. As a Society and as British Exhibitors, we are much indebted to those gentlemen for the excellent work which they did, and for the successful result.

Everyone has heard of the wonderful deposit of sulphur in Louisiana and the still more remarkable manner in which that sulphur is extracted, and placed on the surface ready for the market. An excellent exhibition of this sulphur was shown in the St. Louis Exhibition. The specimens are remarkably fine, beautiful in colour and evidently of great purity. The owners claim that the sulphur tests 99.9 per cent., and so far as the appearance goes I have no doubt that that is correct.

Mr. Higgins, Dr. Conroy and myself, who were together on that occasion, were introduced to Dr. William C. Stubbs, the Commissioner for Louisiana, also the State geologist, who received us with great courtesy and gave us much interesting information. It appears that the sulphur mines were discovered by accident, and a very large sum of money is said to have been spent and lost in endeavouring to get at the sulphur by sinking shafts, but the quicksand and the water therein prevented any success by that method. Subsequently, however, Mr. Frasch, of the Standard Oil Co., devised the method of melting the sulphur *in situ*, and forcing it up to the surface in a melted condition. At first the sulphur was melted by superheated steam; it now is melted by superheated water, and it is stated that the borings made by the Company, now working this mine, show that at least 40 million tons of sulphur lie underneath their land. The deposit occurs at about 400 feet below the surface, and for the upper 120 feet the sulphur is of a pure crystalline character. There is a further thickness of about 300 feet more or less mixed with gypsum.

When we were there it was reported that the mine was raising about 1,000 tons of sulphur per day. Reports, however, vary upon this point, but it appears that at all events not less than 500 tons a day are being raised, and the owners of the mines expect to raise a very much larger quantity before long. The expense of labour and fuel in getting the sulphur to the surface is comparatively small, and is stated to be about \$3½ per ton, but how long the borings will last, or, in other words, how many borings it will be necessary to sink for a given quantity of sulphur I believe no one as yet knows. Therefore, the total cost of the sulphur over a long period is at present a matter of conjecture. I see, however, that a cargo of this sulphur has arrived at Marseilles, and I believe several quantities have been shipped to Europe; at all events, there seems to be no doubt that the supply from this mine will quite satisfy the domestic demand. In fact, statistics already show that whereas over 29,000 tons of sulphur were imported into America in October, 1903, only between 2000 and 3000 were imported during October, 1904.

It is an interesting question when and how this sulphur has been deposited. Dr. Stubbs informed us that in this region the sulphur and the oil occur together, and they occur in the lowest tertiary or the upper cretaceous formation. Geologists are not decided upon this point, but they are agreed as to the origin of the sulphur, and the theory is as follows:—Gypsum, limestone and lignite occur together, and it is believed that the sulphur has been formed by the reduction of the gypsum by the underlying lignite, which is also the source of the oil.

Chicago is now a city of two million inhabitants, and celebrated all the world over for its enormous establishments for the killing of cattle and pigs and the preparation of their carcases for food and for food products. In 1833, the inhabitants of Chicago did not number more than 150. The souvenir of Chicago, which was furnished to us as visitors, contained a great number of most astonishing figures; for instance, 26 railways centre in the city, and the mileage of these, which is about one-third the total in the States, or 84,000 miles, handles 41 per cent. of the total freight tonnage of the country, and the railway mileage of Great Britain, Germany, Ireland and France about equals the mileage centring in Chicago.

An area of about 500 acres is covered by the stock-yards, and upon this space are handled daily 75,000 cattle, 300,000 hogs, 125,000 sheep and 6000 horses; the number of people dependent upon this industry is about 450,000.

One of the most vivid impressions which I have brought

home from America is that ceaseless and superabundant energy of the inhabitants. Exhibitions of force seemed to give them more satisfaction than mere force does to the people of other countries. I remember one Sunday morning, whilst walking along the principal road a beautifully wide one of Chicago, noticing how every driver of a motor car seemed intently anxious to get the utmost possible out of his machine. It did not appear to be their object to enjoy the air or see the country, but their one idea seemed to be to go as hard as they could, and this seems to apply to them in every relation of life.

At Detroit, we went through the enormous pharmaceutical manufacturing establishment of Messrs. Parke, Davis & Co. The visitors were the guests of this firm for the day. We were shown the laboratories and we received a very interesting lecture from one of the principal men in the laboratory, on the subject of the preparation of drugs, the efficiency of which could not at present be tested by any chemical method, but only by practical trial. For instance, drugs acting upon the heart. The lecturer claimed that his firm produced absolutely uniform results in drugs of this description, by the only method at present possible, that is, the experimental method upon living animals. These experiments apparently are carried out with all the humanity possible, dogs are usually chosen for the purpose and are put under an anæsthetic, and are continually under an anæsthetic during the whole of the experiment, which sometimes lasts for two or three days. The animal is not allowed to return to consciousness, but its life is terminated when the experiment is finished, and without the slightest suffering to the animal. Messrs. Parke, Davis & Co., of course, have a large quantity of beautifully designed machinery for the manufacture of their various preparations, essences, pills, capsules, and the labour-saving machinery is as conspicuous in the manufacture of these preparations, as in any industrial operation that we had the pleasure of seeing in the United States.

At Detroit I was obliged to sever my connection with the Society of Chemical Industry party, owing to some business calls in other directions. The party afterwards went to Buffalo, Niagara and Boston, and so round to New York and home.

DISCUSSION.

Mr. MAX MUSPRATT said that what interested chemists most were those processes which centred round the great water powers of America. At Niagara, of the many industries worth mentioning, in the first place was the carbide industry. Calcium carbide was industrially discovered in America, an exceptionally good country for the development of that industry, because it had so many isolated towns and villages without coal-pits or water power, but wanted a cheap illuminant. At present something like 40,000 tons of carbide were manufactured annually at Niagara, where they had an extremely efficient staff both of engineers and chemists, who were always improving their methods and discovering new variations, both in the manufacture and application of carbide of calcium. The power used was about 30,000 h.p. per annum. Carborundum was an extremely interesting product; but carborundum, though important and interesting, was not an epoch-making substance in the evolution of chemistry. Among the processes which would have been of great interest to him, if he could have obtained details, were the caustic and bleach works. One had an idea that the American and English works had drifted apart in their method of manufacture, but nothing definite was known. Chlorate of potash was also manufactured at Niagara, and one had reason to think it was working satisfactorily from the point of view of the owners of the works there. But apart from Niagara, although there were other powers in the United States, he thought that the electro-chemical processes were not making any great headway. In the hands of the particular companies situated at Niagara, the processes seemed successful; but attempts made in Massachusetts and in Michigan to establish chemical works for the production of alkalis and bleach were apparently not very successful. There

factors that were making the American process extremely different from the one of which we had heard. First of these was the fact that a large concentration of Americans had clustered at all the works, so that a process was being worked satisfactorily in the States, that it was not a technical success might mean that the people who managed it were so worried that they ran any process off the top of their heads, and Germany a good deal less so, at the front. In the States he was struck by the fact that the best processes were always those that used of this enormous power which the States had kept in such a country. The second factor was connected with the question of combination, and the question of protection, which also complicated things very much. Products that had a 25 per cent. protection could be manufactured by a 10 per cent. process successfully, so, unless one had an opportunity of examining the books and the processes very minutely, it was impossible to conclude that because a thing was a commercial success in the States it was a real technical success. The States had not adopted the contact process for sulphuric acid manufacture, but they had developed the ordinary lead chamber process to a very good point, and they certainly had good vitriol plants, well managed. In alkali, the ammonia-soda process at Syracuse was supreme; and in Michigan there were also ably conducted ammonia-soda works. In Canada the natural resources were very great, at any rate for the primary industries, but the power of capital was so great that he was inclined to think that technical development might have been checked in even greater degree than in the States. In Canada they had exactly the American spirit of force and energy, and expected quick and rapid returns, and when a man was making 40 per cent. he did not perhaps bother about the fine details of manufacture to the same extent as he had to do in an old country. One of the interesting industries in Canada was wood distillation, to which he believed there was a great future. Certainly it was in very energetic hands, and although the technical side of it was nothing like so well developed as in Germany, where they had not the same natural advantages, the industry was an important one, and a very growing one.

Dr. Coxgrove also gave a short account of his visit to America. In the various works they visited, he said there was noticeable a great deal of organisation—a great deal of method even in works of small size, and in which in this country comparatively little method would be observed. As regarded the efficiency of the staff, a great deal was due to the way in which they were trained. They went from the universities into business, and started at the bottom. Thus in engineering works they began by oiling the engines; if they were smart they rose gradually, and the result was that when they did come to the top they had, in addition to their scientific training, a thorough practical knowledge from start to finish. They were thus capable of leading and managing. Another point which struck him was the way in which the larger concerns encouraged research. Messrs. Parke, Davis and Co., for example, had a chemical laboratory in which were employed 26 chemists, 15 of whom, highly educated men, were doing independent research. Each had a room to himself, and was able to pursue his researches uninterrupted, reporting when he had results to give. America was undoubtedly a very great country. It had great resources, which one could not help but feel on walking through two or three of the halls of the St. Louis Exhibition. Going through the agricultural hall there was a wealth of agricultural produce all round. Similarly in the building devoted to metallurgy there was an equal wealth of minerals. They were told that the mineral resources of the States had only been scratched at up to the present. In the Exhibition they were shown a mineral which was stated to contain almost every known element, including 9 ozs. of platinum to the ton. The chemical processes, however, which they were permitted to view, were not in the new branches. With regard to the processes he had the privilege of seeing he did not think the Americans were ahead of us in their methods of

manufacture, or that they could produce more cheaply; but they seemed to carry more method into the thing. Niagara was, of course, the point which they thought would be the most interesting to them, and was the industrial centre they wished to have the opportunity of seeing in some detail. Unfortunately, they were only allowed to go into one of the chemical works, viz., that of the Acheson Graphite Co. Mr. Muspratt had made some remarks as to the American methods in electro-chemistry, having perhaps grown apart from English methods. From conversations on the spot he could say that had taken place to some extent; in fact, in one of the electrolytic processes a large share of success was due to the very considerable modification in the construction of the cell.

Meeting held at Manchester, on Friday, December 2nd, 1904.

MR. J. CARTER BELL IN THE CHAIR.

NOTE ON THE ACCURACY OF THE DRY ASSAY OF GALENA IN AN IRON CRUCIBLE.

BY W. F. LOWE, A.R.S.M., F.I.C.

Although the dry assay of galena in an iron crucible is so largely used in the buying and selling of lead ores, its accuracy is often questioned: success with it is, however, a matter requiring experience, and to those who have had some practice with it, it will yield very good results indeed. The method is so well known, that a description is not required; it may be mentioned, however, that it is advisable to remove the assay from the furnace as soon as it appears to be reduced, and, in my own practice, I do not keep it in longer than 5 to 10 minutes.

In Percy's Metallurgy, Vol. Lead, it is stated that the purest galena by this method yields from 84½ per cent. to 85½ per cent., whilst the theoretical amount of lead in lead sulphide is 86.58 per cent. Phillips states that the method with pure galena yields 84 per cent. My own experience, which is a fairly large one, is that better results than these can be obtained, for samples of dressed ore as sold at the mines, and in which a little blende and calcite can be seen with the eye, yield from 83 per cent. to 84 per cent. of lead.

Recently, a sample of very pure galena sold as Potter's Lead (*i.e.*, hand-picked ore for use in the Potteries), when assayed in the usual way, yielded 85.86 per cent. of lead. In order to see that it had not been assayed under specially favourable conditions, it was assayed again a few days later, and then yielded 85.87 per cent. As this sample represented 18 tons of ore, it was not likely to be absolutely pure, and it seemed of sufficient interest to estimate the amount of impurity present. This was done, and the only foreign matters found were 0.22 per cent. of Fe_2O_3 , and 0.3 per cent. of CaO . As the lime was present as carbonate, and 0.3 per cent. of CaO equal 0.53 per cent. of CaCO_3 , the total amount of impurity was 0.75 per cent. After taking this into account, it will be seen that the yield of lead, by dry assay, differs from the theoretical by only $+0.02$ per cent. to $+0.03$ per cent.

DISCUSSION.

Mr. H. L. TERRY regretted that Mr. Lowe was unable to be present to reply to the discussion. The accuracy of the dry assay was often called into question, and there were plenty of instances on record where considerable discrepancies existed between the figures yielded by the dry and wet assay. It was the common practice in the North of England for the dry assay to be used; the lead smelters preferred it to the wet because it showed the results they might expect in practice. At the same time, the mine owners were often inclined to grumble, because they knew that the method favoured the smelter rather

than themselves. His own experience bore this out, though he might say that the error in the case of galena dressed up to 77 or 80 per cent. was but trifling; it was rather in assays of the house or crude ore that the error became significant. In the case of low-grade ore, indeed, he had known the error to be as much as 25 per cent.—a fact of importance where the valuation of a mining sett was in question. Mr. Lowe certainly seemed to have obtained some very accurate results, though he was rather doubtful whether the smelters would extend a complete welcome to the improved method if it came into general use.

Mr. F. SCUDDER endorsed Mr. Terry's remarks. Some years ago he (Mr. Scudder) had extensive practice in analysing galena by the Flintshire method, and it was most difficult to obtain results within $2\frac{1}{2}$ per cent. There was a great difference between the dry and wet methods, and Mr. Lowe should have given the exact fluxing mixture for the dry assay of galena. It was well known that Welsh galenas were obtained from good ores. The paper was deficient with regard to the exact methods adopted in conducting these analyses, and he hoped Mr. Lowe could see his way to furnish the details of his process. Galenas contained about 2 to 2.5 per cent. of oxygen, and it would be of great interest if the author of the paper could throw some light on the form which the oxygen assumed in these ores.

Mr. W. F. LOWE has furnished the following reply:—

My object in writing this paper was simply to point out that the dry assay of lead is much more accurate than is generally supposed, and for rich ores will give very good results, whilst the time occupied is very short. As there is nothing new in the method I use, it is fully described in Percy's Metallurgy, and is the one usually employed, I did not think it necessary to go into details, but I will do so as there is a request for them.

32.666 grms. of ore (one assay ton), 3 grms. of argol, and 30 grms. of carbonate of soda are mixed and placed in a bright copper scoop, the charge occupying the front portion of the scoop, and behind it is placed about 10 grms. of borax; the charge is then shot into a red hot iron crucible which has been removed from the furnace for the purpose. The crucible is replaced and kept in the furnace until the charge has run down and is quiet and clear on the surface; the crucible is then given a shake with the tongs, so as to clean the sides with the molten flux, and the assay is then poured into a conical iron mould, and the hot crucible tapped on the top of the furnace to collect any shots of lead which are poured into another mould, and weighed with the large button. As soon as the flux has set, the lead button is knocked off, hammered into a cube, marked, washed, dried and weighed. The crucibles must be of wrought iron, as cast iron pots are useless. The crucibles I use are made for me by the Sandycroft Foundry Co. They usually stand from 20 to 30 melts; they are scraped out with an iron scraper between each assay, and before the first assay, a charge of borax is melted down and run out, except in the case of a new crucible. The chief point of all is to remove the assay as soon as reduction has taken place, for if it is left in the furnace, even for a very few minutes after this, a loss will take place; the temperature, also, must not be too high. I prefer ordinary borax to the anhydrous, as it swells up and cleans down the sides of the crucible. When the silver is not required, 30 grms. of ore are taken, but if the silver also has to be estimated, as is usually the case, the assay ton is more convenient, as it gives the silver direct, without calculation or the use of tables, for each mg. of silver is equal to an ounce per ton of 2240 lbs.

I quite agree with Mr. Terry that the method is not suitable for poor ores, and for such I use a wet method, but it can be used for most samples of dressed ore. A plan adopted by an American assayer for poor lead ores would, I think, very likely make the method applicable. He adds a known weight of litharge sufficient to bring up the lead to about 80 per cent., and then assays the ore in the dry way. The method generally known as the Flintshire Assay is one in which about 1 lb. of galena is melted in a wrought iron bowl without any flux.

The oxygen referred to by Mr. Scudder is present in galena was most likely due to a little cerussite, as this mineral, carbonate of lead, very frequently occurs with galena.

Newcastle Section.

Meeting held at Armstrong College, on Thursday, December 15th, 1904.

DR. J. T. DUNN IN THE CHAIR.

DETERMINATION OF SULPHUR IN PYRITES, BY LUNGE'S METHOD.

Communicated from J. and H. S. Pattinson's Laboratory, Newcastle-on-Tyne, by THE LATE H. SALVIN PATTINSON, F.R.S., F.I.C.

The experiments in the paper were undertaken with a view to comparing Lunge's method of determining sulphur in pyrites with that published by Silberberger (this J., 1903, 1149). The details of the comparison of the two methods were communicated to Prof. Lunge for embodiment in a report to the International Committee on Analytical Methods, and need not be given here; it is enough to say that Silberberger's method was found to give accurate results when carefully carried out, but that it is very much more troublesome to work than Lunge's and is also expensive, from the large quantities of alcohol required. During the inquiry, however, several points arose requiring investigation, and it seems desirable to place on record the experiments that were made to decide them, and the results obtained.

The sources of error in the determination of sulphur in pyrites by barium chloride are due to (1) retention of iron by the barium sulphate precipitate, (2) Solubility of barium sulphate in the filtrate and wash waters, (3) Co-precipitation of barium chloride with the barium sulphate. To avoid (1) Lunge precipitates the iron as ferric hydroxide by means of ammonia, and filters off this precipitate before precipitating with barium chloride; but by so doing he introduces (4), the possibility of carrying down with the iron some of the sulphuric acid in the form of basic ferric sulphate.

The analyses of pyrites mentioned in this paper were carried out by Lunge's method, as described in his "Chemisch-Technische Untersuchungs-Methoden," 1899, Band I., 245, with certain slight differences or more exact details, the reasons for which will appear in the sequel.

The two details which it appeared to me were not given with sufficient explicitness, in the published descriptions of Lunge's method, are the following, viz.: The quantity of ammonia to be added in excess when precipitating the ferric hydroxide, and the excess of HCl to be added to the solution previous to precipitating with BaCl₂. I have made a number of experiments upon these two points, and I will first deal with those relating to the excess of HCl. The effect of adding a very slight or a greater excess of HCl is seen in two ways—its influence upon the physical character of the BaSO₄ precipitate and upon the retention of BaCl₂ by this precipitate. The rate of addition of the BaCl₂ has also possibly something to do with the retention of BaCl₂, but this point I have not fully gone into. Suffice it to say that whether the BaCl₂ solution (about 20 c.c.) be added over 2 minutes or over 5 minutes, there is no evidence of these different rates affecting the results.

Table I. shows the influence on these two points of the variable acidity of the solution in which the BaSO₄ was precipitated. Some of the precipitates were formed from solutions of normal H₂SO₄ neutralised with ammonia, and in some cases excess of ammonia added and then HCl in excess, others from solutions obtained in the course

at the analysis of pyrites. In each case, the precipitate of BaSO_4 weighed about 1.75 gm., and was fused in a muffle-furnace with 1 gm. of sodium carbonate. From the

amount of chlorine found in each case was subtracted that found by a blank experiment with the sodium carbonate alone.

TABLE I.

Showing the effect of the acidity of the solutions on the nature of the BaSO_4 precipitate and the retention of BaCl_2 .

No. of Expt.	Volume of liquid.	Excess of NH_4HO neutralised by HCl	Excess of HCl	Excess of HCl per 100 c.c. of liquid	Rate of adding 20-23 cc. BaCl_2 solution.	BaCl_2 in BaSO_4 ppt. calculated from AgCl obtained	Nature of BaSO_4 ppt.

From this table it may be seen that the presence or absence of ammonium chloride within the limits used has apparently no influence upon the retention of chlorides or upon the character of the precipitate of BaSO_4 . The degree of acidity, however, has a very important effect. If there be less than 0.17 c.c. of HCl per 100 c.c. of liquid, the precipitate of BaSO_4 retains BaCl_2 in objectionable amount, and is usually fine and settles slowly. When the acidity is increased to about 0.3 c.c. per 100 c.c. of solution, the retention of BaCl_2 is insignificant, and the precipitate is usually dense and settles almost immediately. Experiment 25, in which the excess of HCl was 0.7 c.c. per 100 c.c. caused a precipitate which was not quite so free from BaCl_2 as when about 0.3 c.c. per 100 c.c. of solution was used, but which settled fairly rapidly. Only one experiment was made with an excess of 0.7 c.c. per 100 c.c.

The other detail to which I have directed attention is the excess of ammonia necessary to be added to precipitate the ferric hydroxide. The experiments which I have made on this point have also been directed to clear up two other points, viz., the best temperature at which to effect the precipitation of the ferric hydroxide so as to obtain a precipitate free from sulphuric acid, and the conditions which influence the bulk of liquid necessary to wash the ferric hydroxide precipitate thoroughly. Lunge, and his pupils at the Zurich Polytechnik, have no difficulty in obtaining the ferric hydroxide precipitate free from basic ferric sulphate: nor has Treadwell, although his procedure differs somewhat from Lunge's in that he precipitates in the cold, and, whilst stirring continually, brings the solution to the boiling point, but does not continue to boil, while Lunge precipitates in the cold, heats to 60-70° C., and allows to stand 15 minutes. Neither Lunge nor Treadwell is explicit about the excess of ammonia to be added. Lunge, in the *Alkali-Makers' Hand Book* (Lunge and Hurter, 2nd. Eng. Ed., 1891, p. 93), says, "The filtrate and washings (*i.e.*, from the insoluble residue) are saturated with ammonia, avoiding much excess of it and keeping the hot liquid about 10 or 15 minutes before filtration, but not boiling till all the ammonia is expelled (in which case the precipitate contains some basic sulphate)." In his work on Sulphuric Acid and Alkali (2nd Eng. Ed., Vol. I., p. 56), he says, "The filtrate and washings are saturated with ammonia, avoiding much excess of it; the mixture is kept at a moderately warm temperature for about 10 minutes (at the expiration of which time it ought still to smell of ammonia very distinctly, not merely faintly), and the precipitated ferric hydrate is filtered off while the liquid is still hot;" and in his *Chemisch-Technische Untersuchungs-Methoden* (Ger. Ed., 1899, Vol. I., p. 245), the following is a translation of his description of this part of his process: "The filtrate,

together with the washings, is saturated with ammonia in not too great excess, and the liquid warmed at 60-70° for 10-15 minutes, but *not* heated to boiling; it must always still smell strongly of ammonia (otherwise the precipitate may contain some basic ferric sulphate)."

Treadwell, in his "Analytical Chemistry" (Eng. Ed., 1904, Vol. II., Quantitative Anal., p. 282), says:—"To separate the iron, the cold solution is treated with an excess of ammonia in the cold (*sic*) (to prevent the formation of a basic ferric sulphate), and afterwards heated to boiling point, with constant stirring"; and to this there is a foot-note as follows:—"After the solution is made alkaline with ammonia, it can be heated to boiling without any danger of forming a basic ferric sulphate. The latter would be formed if the weakly acid solution were boiled. Except (the English Edition says 'even,' but this is a mistranslation of the German 'ausser,' which stands in the German Edition) when the pyrites contained considerable copper, the author has never found sulphuric acid in the ammonia precipitate when the above directions are followed."

But, notwithstanding the fact that Lunge and Treadwell and their pupils are successful in precipitating the ferric hydroxide free from basic ferric sulphate, it is an undoubted fact that other chemists find this a difficulty. Not only have we found it so in our own laboratory, but I have private information from other and well-known laboratories that the same difficulty exists.

It occurred to me that the solution of the difficulty might be found in the addition of at least a minimum excess of ammonia. I found that an excess of 0.5 c.c. of ammonia made the solution smell quite distinctly of ammonia, and the solution might even be considered by a person sensitive to ammonia fumes to smell strongly of ammonia after it had stood at 60-70° for 15 minutes in a covered beaker. I began by adding this excess, and increased it in other experiments up to 10 c.c. under the conditions of temperature given in Table II.

The solution used was in all cases 15 c.c. of normal H_2SO_4 , containing ferric chloride equivalent to 0.21 gm. of iron (these being the amounts of sulphuric acid and iron in the solution of 0.5 gm. of a pyrites containing about 48 per cent. of sulphur). To this was added 1 c.c. of HCl and 150 c.c. of water, so that the total volume of the solution was about that obtained after oxidising 0.5 gm. of pyrites, and filtering and washing the insoluble residue according to Lunge's method. The ferric hydroxide precipitates were tested for barium sulphate by fusing with 4 grms. of sodium carbonate in a muffle-furnace, deducting from the weight found in each case that obtained from 4 grms. of the sodium carbonate itself by precipitation with barium chloride.

I do not wish to draw too sweeping conclusions from the results shown in this table; but, as far as they go, they indicate that:—

(1) With a distinct excess of ammonia, even when precipitation is effected in the cold, the precipitate may contain very considerable quantities of basic sulphate.

(2) The tendency to the formation of basic sulphate increases with the temperature, so that at the boiling point with 3 c.c. excess of ammonia, the precipitate may contain as much as when precipitated in the cold with only 0.5 c.c.

(3) The amount of basic sulphate in the precipitate diminishes as the excess of ammonia increases. With 5 c.c. excess in the cold the precipitate is free from it, and even when precipitated at the boiling temperature, the amount is only equivalent to 0.05 per cent. of sulphur in a pyrites when 0.5 gm. is operated upon.

(4) It is shown by experiment 43 that at the boiling point ferric hydroxide will react upon ammonium sulphate, with production of basic ferric sulphate. Speaking generally, therefore, it is inadvisable to boil the solution,

lest, through expulsion of the excess of ammonia, this reaction should occur.

(5) Having regard, not only to obtaining a precipitate free from sulphate, but also to the rapidity of filtration and washing, and to minimising the bulk of fluid for subsequent operations, it seems advisable to precipitate with not less than 5 c.c. excess of ammonia, at whatever temperature the precipitation and the filtration be carried out.

With regard to the influence of ammonium salts in increasing the solubility of barium sulphate, the following experiments (Table III.) show that the presence of ammonium chloride, in quite considerable amount, has but little influence in increasing the solubility of BaSO₄ under the conditions of its precipitation by Lunge's method, and that an excess of from 1.2 c.c. of HCl in 300 c.c. of liquid is also quite permissible.

I may remark that usually all the soluble BaSO₄ is obtained by evaporating the filtrate to dryness on a water bath, and that it is quite exceptional to find any still remaining in solution, so that the expulsion of the ammonia salts from the dry residue is unnecessary.

8.	" 420 cc.	5 cc.	do	1 cc.	Not tested	0.0010 (total in solution A+B).

The modifications in Lunge's method, then, mentioned above, are as follows:—

(1) The ferric hydroxide was precipitated at a temperature of 70°C . and allowed to stand 10 minutes at this temperature instead of precipitating in the cold and then warming to 60°C . and keeping at that temperature for 10–15 minutes.

(2) The excess of ammonia added was 5 c.c. of ammonia sp. gr. 0.888. The necessary excess is not stated by Lunge.

(3) The volume of solution after washing the precipitate of ferric hydroxide was found to be 340 c.c. The volume was not reduced by evaporation, but the solution was exactly neutralised at once (using methyl orange as indicator), with HCl , an excess of HCl added and the BaSO_4 thrown down by BaCl_2 in the boiling hot solution.

(4) The excess of HCl added was 1 c.c. of HCl sp. gr. 1.17. The amount of excess most desirable is not stated by Lunge.

The statement is made by Lunge and also by Treadwell that the volume of liquid after washing the ferric hydroxide precipitate can be easily kept as low as 300 c.c., and that, if it be more, it should be concentrated before precipitating with BaCl_2 . I find it not very easy to keep the bulk of liquid as low as 300 c.c., though, with care, it can be done. But even should the volume reach 400–450 c.c., I have found it quite unnecessary to concentrate the liquid.

I find the time required to wash the ferric hydroxide precipitate properly is, as stated by Lunge, from $\frac{1}{2}$ –1 hour.

In the analyses of the samples of pyrites the amount of barium sulphate carried away in solution in the filtrates and wash-waters was determined and allowed for; the amount contained in these usually amounted to 0.003 grms. under the conditions of the experiment. It is clear that if the reagents employed were absolutely free from sulphur, this amount would always have to be determined (or a constant allowance made). If, however, as is usually the case, the reagents used contain more than this amount, then not only the filtrate from the main barium sulphate precipitate, but also the filtrate in the "blank," carries away this amount of barium sulphate. Each of these precipitates, then, being below the truth by the same amount, the difference between them is the same as though both were accurate, and there is no need to evaporate the filtrates and determine the barium sulphate they contain. It is thus an advantage that the reagents should contain sulphur to this extent.

Finally, it may be mentioned that the figures obtained for the sample of pyrites tested, which was sent to me direct from Dr. Lunge, and three determinations of the sulphur in which were made, agreed among themselves within 0.02 per cent., and differed from two determinations of Dr. Lunge's on the same pyrites by less than 0.1 per cent.

Dr. Lunge was good enough, at Dr. Pattinson's request, to make a number of experiments on the three points of (1) temperature of precipitation of the ferric hydroxide, (2) amount of excess of ammonia advisable in precipitating the ferric hydroxide, (3) amount of excess of hydrochloric

acid advisable before precipitating with barium chloride. The results of these experiments, and Dr. Lunge's general conclusions, are as follows:—

(1) The temperature of precipitation of the ferric hydroxide is of no consequence, so far as the freedom of the precipitate from basic sulphate is concerned; but precipitation at 70°C . has the advantage over precipitation in the cold and subsequent heating that the ferric hydroxide can be more quickly washed. (2) An excess of ammonia of 2 c.c. (sp. gr. 0.915) is sufficient to avoid any sensible contamination of the ferric hydroxide with sulphate. This excess may be increased without disadvantage to 7 c.c. (equivalent to 5 c.c. of solution of sp. gr. 0.880); but with larger excess, say, 15 c.c., the ammonium chloride formed keeps sensible quantities of barium chloride in solution. (3) If the excess of hydrochloric acid is greater than 1 c.c. (say, 3–6 c.c.), sensible quantities of barium chloride are precipitated with the sulphate.

Accurate results are obtained by following Dr. Pattinson's recommendations (5 c.c. of ammonia and 1 c.c. of hydrochloric acid beyond the quantities required for precipitation or neutralisation), and it is quite unnecessary to determine the quantities kept back in solution or in the precipitates, as the errors in question are balanced by the sulphuric acid contained in "chemically pure" reagents, obtained from first-class dealers.

SOME SOURCES OF ERROR IN SULPHUR DETERMINATIONS.

Communicated from J. and H. S. Pattinson's Laboratory, Newcastle-on-Tyne, by JOHN PATTINSON, F.I.C., AND J. T. DUNN, D.S.C., F.I.C.

Two sources of error in sulphur determinations, both of which may assume considerable importance where small amounts of sulphur have to be determined, have recently come under our notice.

Some of the red india-rubber corks commonly used for wash bottles are acted on by boiling water or steam, and give up sulphuric acid to the water. This is probably due to the oxidation of sulphur used for vulcanising or of metallic sulphides (such as antimony sulphide) which have been added to the rubber. If such a bung be boiled for a few minutes with water and the water be then tested with barium chloride it will be found to contain an amount of sulphur sufficient to introduce serious error into the determination of sulphur in, say, an iron or steel.

The other source of error lies in the presence of soluble sulphur compounds in commercial barium chloride. We find that many samples of barium chloride when dissolved in water, and oxidised with a drop of nitric acid or bromine and boiled, yield a precipitate of barium sulphate. This is no doubt due to the barium chloride having been manufactured from heavy spar by reduction to sulphide and subsequent treatment with hydrochloric acid, some soluble unoxidised sulphur compound being retained in the crystals of barium chloride. We have

found, in a sample of chloride of barium sold as pure, a quantity of sulphur which would, in testing an iron or steel, have increased the sulphur result by 0.02 per cent.

New York Section.

November 25, 1904.*

DR. RUSSELL W. MOORE IN THE CHAIR.

THE USE OF TANNIC ACID IN DETERMINING ALUMINA.

BY ROBERT E. DIVINE.

In carrying out a series of complete analyses of clay, considerable difficulty was experienced by the writer in accomplishing a sufficiently rapid and accurate determination of alumina. It is well known to those who are familiar with this determination that to filter alumina and wash it free from chlorides is a difficult matter. The use of tannic acid has afforded the writer such valuable results that it seemed desirable to invite general attention to its value in effecting the precipitation of alumina in a form which admits of satisfactory and easy filtration and washing. In this connection it is assumed that it is always necessary to make a double precipitation of alumina if it is associated in solution with any considerable quantities of other salts.

If to a solution containing approximately 0.1 gram. of alumina there be added 2 c.c. of a 2½ per cent. solution of tannic acid, then ammonia in slight excess, and the solution boiled until the odour of ammonia has almost disappeared, alumina is precipitated in a form which filters very readily with the aid of a "suction tube," and permits of washing free from chlorine. Some doubt was at first entertained as to whether, in presence of considerable quantities of lime and magnesia, the presence of tannic acid would interfere with their separation, and the subjoined experiments were carried out to decide this point. The results are in every way satisfactory.

Solutions were made up as follows:—

1. Standard aluminium chloride solution, made by dissolving metallic aluminium in hydrochloric acid, and containing 0.095 gram. alumina in 25 c.c.
2. Standard lime solution containing approximately 0.1 gram. CaO in 25 cc.
3. Standard magnesia solution, containing approximately 0.1 gram. MgO in 25 c.c.
4. A solution containing 40 grms., each of potassium and sodium chlorides (80 grms. of salts) per litre.

These solutions were carefully standardised, and a blank determination of alumina and magnesia made on the mixed solutions, leaving out in each case the standard aluminium and magnesia solutions respectively. Then 25 c.c. each of the aluminium chloride, lime and magnesia solutions, and 50 c.c. of the salt solution were measured into a platinum dish, alumina precipitated with aid of tannic acid as above, filtered and washed with hot water three times, then washed back into the platinum dish and redissolved in hydrochloric acid, reprecipitated with ammonia and washed practically free from chlorine.

The filtrates from alumina were concentrated in a platinum vessel, made alkaline with ammonia, and the slight trace of alumina so obtained filtered off and added to the main precipitate; then the lime was precipitated with ammonium oxalate and weighed as CaO. It was found necessary, in presence of so much magnesia, to make a second precipitation of lime in order to completely free it from magnesia. Accordingly the ignited calcium oxalate was dissolved in dilute hydrochloric acid and reprecipitated with ammonium oxalate and ammonia.

In standardising the aluminium chloride solution tannic acid was used with this modification: the filtrates from alumina were evaporated with addition of a little

sulphuric acid, and finally ignited until sulphuric was expelled and all tannic acid removed; the residual trace in the platinum dish was treated with concentrated hydrochloric acid and finally with ammonia, and the trace of alumina filtered off and added to the main precipitate. Results follow:—

Standards.		Found in mixture	Blank.	Corrected.
Alumina Al_2O_3		Al_2O_3	Al_2O_3	Al_2O_3
1	0.0950	0.0953	0.0002	0.0951
2	0.0945	0.0952	0.0002	0.0950
3	0.0950	0.0952	0.0002	0.0950

LIME, CaO.

Standard.		1st precipitation.	2nd precipitation.
1	0.1030	0.1072	0.1030
2	0.1024	0.1057	0.1023
3	0.1027	0.1063	0.1019

MAGNESIA AS $Mg_2P_2O_7$.

Standard.		Found in mixture.	Blank.	Corrected.
1	0.2750	0.2805	0.0015	0.2790
2	0.2757	0.2799	0.0015	0.2784
3	0.2764	0.2817	0.0015	0.2802

The results on magnesia calculated to MgO are:—

Standard.		Found in mixture (corrected).	
1	0.0998 MgO	0.1010	MgO
2	0.0998 "	0.1008	"
3	0.1001 "	0.1014	"

In the above alumina determinations, the trace of alumina found in the filtrates was ignited and weighed with the main precipitate. It was thought of interest to make a few determinations without recovering the alumina in filtrates, and to make a few with addition of ammonium chloride to the aluminium solution before precipitating. In the first six of the following determinations 25 c.c. of aluminium solution was taken, in the remainder double this amount:—

1	0.0939	Without ammonium chloride. Alumina in filtrate not recovered.
2	0.0938	
3	0.0943	
4	0.0937	With 1 gram. ammonium chloride. Alumina in filtrate not recovered.
5	0.0940	
6	0.0950	
7	0.1895	Alumina in filtrate not recovered.
8	0.1894	

Four determinations were now made to ascertain how much alumina passed into the filtrate. Ammonium chloride was added in each case.

Main precipitate.		Residual in filtrate.	Total.
Al_2O_3		Al_2O_3	Al_2O_3
9	0.1897	0.0002	0.1899
10	0.1892	0.0002	0.1894
11	0.1902	0.0002	0.1904
12	..	0.0002	..

Small amounts of iron precipitated with alumina do not interfere with filtration. It is the writer's belief that large quantities of ferric hydroxide mixed with alumina would filter readily. Pure ferric hydroxide in presence of tannic acid does not filter satisfactorily.

THE DETERMINATION OF ROSIN IN SHELLAC

By A. C. LANGMUIR.

The presence of rosin in shellac has long been suspected and complained of. Always a serious question, conditions of late have become little short of scandalous. This has been due to the scarcity of shellac and the marked increase in its price. To be able to buy the profit to be made in selling rosin costing 2 or 3 cents in the form of shellac at 50 cents and undeterred by any fear of a complaint fortified by incontrovertible chemical evidence as to the percentage of rosin present, adulteration has gone on unchecked. Of course, that a shellac has given trouble in bleaching, or worked badly in a varnish or cement, are met by the statement that in colour and general appearance the sample is up to the standard. As long as these points are the only ones considered between sellers and buyers the condition of the trade will remain as it is, and little improvement in quality can be looked for. It is only by a systematic chemical examination of shellac that progress can be made. Against this, in the past, has stood the lack of an accessible method described in detail, so that concordant results could be obtained by different chemists. I trust that the method to be described will prove of service in this respect.

The literature on the testing of shellac is meagre. Schmidt and Erban (*Zeits. angew. Chem.*, 1889, 35), in a study of the iodine absorption of resins, find, in the case of brown shellac, an absorption of 8.3 and 6.0 per cent. Curiously, with an orange shellac they found no absorption. Williams (*Chem. News*, 58, 224) obtained iodine figures for various grades of shellac ranging from 17.5 to 28.7. Some of these were unquestionably impure. Parry (*Chemist and Druggist*, Jan. 31, 1903) finds that pure lacs give iodine numbers varying between 7.5 and 11. Rudling (*Chem. Rev. Fett u. Harz Ind.*, 1903, 51) found values between 3.6 and 7.5, button lacs 19.0 to 23.3. Tschirch (*"Harz und Harz behälter"*) and Dieterich (*"Analyse der Harze"* and various papers) urge the uselessness of iodine absorption tests in the valuation of rosins. In so far as this applies to shellac they are mistaken. Worstall (*J. Amer. Chem. Soc.*, 1903, 860) draws the same conclusion in regard to copals. The variation between iodine values as obtained by different observers, cannot be urged as an objection against the method, for (1) Their samples may not have been pure. (2) It will be shown that conflicting results are obtained by variation in the details of the method.

Mangold (*Zeits. anal. Chem.*, 1894, 477) proposes the use of the Hübl method in determining the proportion of rosin and shellac in sealing wax, forgetting that the presence of turpentine would render the method useless. Ulzer and Defris (*Zeits. anal. Chem.*, 1897, 36) base a separation on the difference of behaviour of the rosin and shellac acids in Gladding's and Twitchell's methods. There are many sources of error, however, and the method is only a rough approximation, although Parry, in a modification of his own, obtains fair results. Dieterich (*Chem. Rev. Fett u. Harz Ind.*, 1901, 223), after trying to solve the problem by determinations of the acid, ester and saponification numbers, concludes that such determinations are worthless, on the ground "dass die Grenzzahlen der Handelsorten sich in erschreckend weiten Bahnen bewegen." He falls back on the action of solvents as offering the only method leading to quantitative results. Tests quoted by him, however, are far from encouraging.

Petroleum Ether Extraction. Rosin is almost completely soluble in petroleum ether, shellac only sparingly. A separation of a fused mixture of the two is practically impossible, however, as the insoluble shellac protects the rosin from solution. This error is the greater the coarser the particles extracted. Shellac wax, which is always present, is soluble in petroleum ether, and is a disturbing factor. It may be removed and the shellac obtained at the same time in a finely-divided state by dissolving the shellac in warm dilute sodium carbonate solution, cooling and filtering off the wax. The shellac is thrown out of the filtrate by acid, filtered on a Buchner funnel, washed and dried. In this condition it is wax-free and in a very finely divided state, offering the most

favourable chances for a successful extraction of rosin.

A button lac of poor quality, known to contain rosin, was finely ground. 5 grms. were extracted in a Soxhlet apparatus for 5 hours. 5.07 per cent. of soluble matter was obtained, largely, wax. An additional treatment of 5 hours gave a further 0.48 per cent. The same button, purified as above and extracted for the same time, gave 1.55 per cent. to the ether. A pure button freed from wax and extracted with petroleum ether gave 0.38 per cent. soluble matter.

Seven bleached shellacs of American make were finely pulverised and passed through an 80-mesh sieve; 10 grms. was extracted for 5 hours. The samples showed respectively, 1.05, 1.08, 1.84, 1.75, 2.43, 4.23, and 4.30 per cent. soluble in petroleum ether. A pure bleached ralli sample gave 3.35 per cent. soluble. The residues from the evaporation of the ether were of a waxy character and showed no indications of rosin.

A poor quality of TX, finely ground and extracted for 5 hours, gave an extract of but 1.6 per cent. A good TX gave 0.6 per cent. The wax was not removed in these tests. Better results were obtained with freshly-prepared artificial mixtures of rosin and shellac, but they were far from the truth.

No safe inferences can be drawn from the results of a petroleum ether extraction, either in the original shellac or the shellac freed from wax.

A published test for rosin is to shake the petroleum ether extract with a little water containing some copper acetate. The ether layer will be coloured emerald green if rosin is present. In our hands artificial mixtures of shellac and rosin failed to show the latter, if less than 15 per cent. were present.

Iodine Absorption.—The most valuable paper yet published on testing shellac is one by Parry (*Chemist and Druggist*, Jan. 31, 1903). The author evidently had access to a great variety of grades, pure and impure, and gives the results of his tests by the iodine method, together with some check analyses on artificial mixtures of rosin and shellac. The latter showed a very satisfactory agreement with the theory. Unfortunately, Parry gives no details whatever as to the kind of solution used, excess of reagent, time of reaction or temperature. It will be shown that these points are of vital importance if the method is to give the same results in different hands.

Parry sets the maximum absorption of a pure shellac at 9 per cent. For rosin, he takes the iodine value at 125. Unless all the conditions of Parry's experiments are known, it would be unsafe for other chemists to adopt these values in their work. Schmidt and Erban, using Hübl's solution, find a value for rosin after 24 hours of 116.8. Worstall obtains a value of 170, using a large excess of Hübl's solution, and standing 18 hours. Ingle (this J., 1904, 425), using Wijs' solution, time $\frac{1}{2}$ to 1 hour, gets 150.

If Wijs' solution, rather than Hübl's, be used in the test for rosin, there is the great advantage that a qualitative reaction is furnished, simultaneously with the quantitative determination. Furthermore, if the details to be given are followed, a higher number for rosin is obtained than heretofore, and the difference between the absorption of rosin and that of shellac is so great, that a very satisfactory basis for calculation is furnished, and the method gains greatly in sensitiveness and accuracy. Shellac stands alone among the rosins in its low iodine absorption. Rosin has an uncommonly high absorption.

Ingle (this J., 1902, 587) states that "all ordinary oils merely reduce the intensity of shade of Wijs' solution by absorption of iodine chloride. Boiled and blown oils colour Wijs' solution red-brown." Shellac has no effect on the colour of Wijs' solution (except after long standing); rosin, even when mixed with shellac in small amount, speedily produces a characteristic red-brown coloration in proportion to the quantity present. By comparison with artificial samples, containing known proportions of shellac and rosin, a fair colorimetric estimation can be made.

There is no trouble whatever in preparing the Wijs' solution. It is more active than the Hanus solution, and a smaller excess is required. The use of the latter should be discouraged as tending to a troublesome duplication of data. Four litres at a time is prepared.

Glacial acetic acid was used. The acid should always be tested for reducing impurities; 51 grms. of finely divided iodine is dissolved at a gentle heat. A portion of about 250 c.c. is set aside; 20 c.c. is taken for titration. Suppose 20.7 c.c. of sodium thiosulphate solution are required. Pure chlorine is passed into the remaining solution until the characteristic colour change takes place; 20 c.c. of this are titrated. Suppose the amount required to be 41.7 c.c. The unchlorinated portion is now added until the titer is reduced to 0.1 or 0.2 c.c. less than 2 \times 20.7 c.c. or 41.4 c.c.

The deci-normal sodium thiosulphate solution is best standardised directly against iodine, sublimed from a tube containing a mixture of iodine with 20 per cent. of potassium iodide, into a weighing bottle 6.5 \times 1.5 cm. diameter. The first vapours are rejected. After weighing the iodine is dissolved in strong potassium iodide solution, and shaken up in the weighing bottle.

The Method.—0.2 gm. of ground shellac is introduced into a 250 c.c. bottle with ground stopper; 20 c.c. of glacial acetic acid is added, and the mixture warmed gently until solution is complete (except for the wax). A pure shellac is rather difficultly soluble. Solution is quicker according to the proportion of rosin present; 10 c.c. of chloroform is added and the solution is cooled to 21° to 24° C. The temperature should be held between these limits during the test. The colour at this stage is a light yellow. Little difference is noticeable between shellacs, the lac dye having little effect; 20 c.c. of Wijs' solution is added from a pipette, the end of which has been heated to somewhat diminish the size of the orifice. The bottle is closed and the time noted. The solution is stood in a dark place. Pure shellacs will scarcely alter the colour of the Wijs' solution. If in small amount, rosin will produce a slowly appearing red-brown colour. In large amount, rosin causes an immediate coloration, increasing in intensity as time passes. After 1 hour, 10 c.c. of 10 per cent. potassium iodide solution is added. The solution is immediately titrated with N/50 thiosulphate solution; 25 c.c. or 30 c.c. may be run in immediately, unless the shellac is very impure, and the remainder gradually, with vigorous shaking. Just before the end, a little starch solution is added. The end point is sharp, as the reaction products of shellac remain dissolved in the chloroform. Any colour remaining after a half minute or so is disregarded.

A blank determination should be run with 20 c.c. of Wijs' solution, 20 c.c. of acetic acid and 10 c.c. of chloroform. The blank is necessary on account of the well-known effect of temperature changes on the volume.

Example:—
Ralli shellac 0.2 gram.
Blank 20 c.c. Wijs' solution 41.1 c.c. hypo. 1 c.c. = 0.123 I
Required in test 35.6

Equivalent to iodine absorbed 5.5
 $5.5 \times 100 \div 0.123 \div 2 = 33.9$ per cent. iodine absorbed.

In testing rosin, 0.15 gm. with 20 c.c. acetic acid, 10 c.c. chloroform and 40 c.c. Wijs' solution is used, the other conditions as to time and temperature remaining exactly as with shellac. With bleached shellacs 0.4 gm. is taken, other conditions remaining unchanged.

Effect of Dirt, Orpiment, Wood, &c.—The only effect noticed was due to the lowering of the iodine absorption by the presence of extraneous matter, less shellac being present to absorb iodine. Except in very dirty samples this error is negligible.

Influence of Time.—This is an important factor, as the following experiments show. Conditions were precisely as given in the method above, except for the variation in time.

Time.	Iodine Absorption.			
	Pure Button Lac.	Light Rosin "M"	"WW"	Rosin.
Hour.	Per Cent.	Per Cent.	Per Cent.	Per Cent.
$\frac{1}{4}$	8.3	222.3	—	—
$\frac{1}{2}$	16.0	233.4	250	—
1	17.2	253.0	—	—
3	18.5	252.0	279.1	—

Influence of Temperature.—Other factor remaining unchanged, the temperature was varied; time, one hour.

Temperature.	Iodine Absorption.	
	Pure Button Lac.	Light Rosin "M"
°C.	Per Cent.	Per Cent.
12	10.8	209.5
22	16.6	235.0
33	22.4	265.6

The shellac and rosin used in each series are the same. The agreement between the respective rosin and shellac values is noteworthy in the two series where the conditions are identical, i.e., shellac 16.0 and 16.6; rosin, 233.4 and 235.0.

Excess of Wijs' Solution.—No experiments were made, a liberal excess being used in all tests.

Effect of Light.—No experiments were made in direct sunlight. Comparative tests on shellac and rosin showed no differences between darkness and moderate light lying outside of experimental errors.

Effect of Shellac Wax.—The wax has an absorption of only 4.5 per cent., and can be disregarded.

An examination of the above results is convincing as to the necessity for keeping the time and temperature constant. If these conditions are observed, concordant results can invariably be obtained on well-mixed samples. Duplicates will not agree as closely as those obtained with non-drying oils, but on account of the enormous difference in iodine absorption between shellac and rosin, a slight variation in the iodine value between duplicates is of little consequence.

Iodine Absorption of Shellac.—A series of standard samples of shellac obtained from a well-known firm gave iodine absorption values of 16.0, 15.4, 16.0, 13.5, 15.1, 19.7, 21.5, 14.8, 17.2, 18.5, 16.0, 31.4, 15.4, 15.4, and 26.5.

The following samples of pure shellac were drawn from cases or large lots:—

Shellac.	Iodine Absorption—Per Cent.
DC	15.9
Good Ralli	16.0
" TN	17.7
" Button (year 1897)	15.8

Many other analyses of shellacs, which have bleached well and gave no evidence of rosin in any way, gave iodine values of 18 or less.

After a consideration of the iodine values of the better grades of standards and the others given, it must be admitted that it is perfectly fair to take as the iodine number of a shellac free from rosin the number 18. If anything, this value favours the dealer, for an ablutely rosin-free shellac undoubtedly has a value below this. Roughly speaking, it could be said that a shellac with a value 18 or less would be a good shellac. Such a shellac will give good results when used; 18 to 23 would be a fair shellac. At 23, various qualitative tests for rosin begin to reveal its presence; 23 to 28 would indicate a poor shellac; 28 to 33 bad. A shellac above 33 is grossly adulterated.

Iodine Absorption of Rosin.—Various rosins show considerable differences in their ability to absorb iodine. The samples are of American origin only:

Rosin.		Iodine Absorption—Per Cent.
" M "	235
W.W. 1	232.5
" 2	228.4
" 3	244.6
" 4	224.3
" 5	217.5
H 1	233
" 2	225.6
Dark 1	175.7
" 2	178

The light coloured, soft varieties of rosin would probably have the highest iodine values, as they contain more residual turpentine after the distillation of the latter.

Calculation of the percentage of Rosin.—In all probability, light rosins are used in the adulteration of button lac. A small piece of rosin found in a case of button was of the light variety, and had an iodine absorption of 202. In another case, part of a stave from a rosin barrel which

had contained light rosin was found. In determining the rosin in button lac, a value for rosin well above 200 should be taken. The average of a number of tests on light rosins was 228, and we have taken this figure as representing a fair average absorption for rosin.

The darker coloured shellacs, Ralli and TN, are probably adulterated with the cheaper dark rosins. The Agricultural Ledger, No. 9, 1901, states that a common grade of American rosin is used in adulterating shellac. The average absorption of such rosins would probably be below 200. On account of the uncertainty, we have preferred to use as a basis in calculating the per cent. of rosin the value 228 for all shellacs, low or high grades. The results are probably closer to the truth in button lacs than in Ralli and TN. By taking the number as high as 228, however, no injustice can be done to the dealer, as any error would be in the direction of low results for rosin.

The use of metallic resins, ester gums, glycerin-rosin compounds, &c., is very unlikely on account of their expense. Metallic compounds would reveal themselves in the ash of the shellac. Analyses of ash from various crude shellacs reveal nothing of this nature. Furthermore, no rosin preparation can be used in which the rosin has lost its solubility in alcohol. Such preparations have a lower iodine value than rosin itself. Any manipulation of the rosin, such as long exposure, heating, &c., would result in a lowering of the iodine absorption due to oxidation. A "W.G." rosin, iodine absorption 226, was pulverized and spread out on glazed paper. After three weeks the iodine value had dropped to 193.

If Y = per cent. rosin, M = iodine number of shellac, N = iodine number of rosin, A = iodine number of mixture

$$\text{Then } Y = \frac{100(A - M)}{N - M}.$$

Taking the iodine numbers of shellac and rosin at 18 and 228, respectively, we have in the case of a TN shellac giving a number of 33.9.

$$\text{Per cent. rosin} = \frac{100(33.9 - 18)}{228 - 18} = 7.6.$$

If a rosin of 190 value had been used we should have 9.2 per cent. rosin. It is safe to say, therefore, that in the above case we are certain that there is at least 7.6 per cent. rosin present.

The following tables, based on the values shellac 18, rosin 228, will give an idea of the relation between iodine absorption and per cent. rosin.

Iodine Number.	Per cent. Rosin.	Iodine Number	Per cent. Rosin.
18.00	—	65.25	22.5
23.25	2.5	70.50	25.0
28.50	5.0	75.75	27.5
33.75	7.5	81.00	30.0
39.00	10.0	86.25	32.5
44.25	12.5	91.50	35.0
49.50	15.0	96.75	37.5
54.75	17.5	102.00	40.0
60.00	20.0		

Extent of Adulteration.—The following results were obtained on samples taken from large lots of TN and Ralli shellac landed at New York during the past year:—

Shellac	Iodine Number	Per cent. Rosin
Ralli, free...	26.5	4.0
" " " " " "	31.4	6.4
" " " " " "	28.7	5.1
TN " " " " " "	35.7	8.4
" blocked " " " " " "	40.1	10.5
" " " " " " " "	42.7	11.8
" " " " " " " "	30.6	6.0
TN, matted " " " " " "	48.9	14.7
" blocked " " " " " "	63.0	21.4
" free " " " " " "	22.9	2.3
" blocked " " " " " "	27.3	4.4
Ralli, free...	19.7	0.8
" " " " " " " "	15.0	—
TN, " " " " " " " "	17.2	—
" " " " " " " "	16.6	—
" " " " " " " "	15.4	—
Ralli, blocked	33.8	7.5

The tests given were taken at random from a large number. The rosin-free shellacs are in a decided minority and the extent of adulteration shown is deplorable.

Any shellac will block if the temperature is high enough, and a blocked article is not necessarily adulterated. Rosin, however, facilitates blocking by lowering the melting point, and there is no doubt of the increase in blocked goods of late.

The adulteration practiced with TN and Ralli is far surpassed in the case of button lacs. With the exception of one brand, not a single sample of genuine button has been met with in the past year.

Button Lac.	Iodine Number.	Per cent. Rosin.
Ruby	73.6	26.5
Sapphire	70.4	25.0
Amethyst	77.4	28.3
Turquoise	68.5	24.0
Special	85.5	32.2

The average of thirty samples of button gave 57.8 iodine absorption corresponding to 18.9 per cent. rosin.

Accuracy of the method.—As a check on the method, a series of melts of shellac and rosin were made. Button lac was used on account of its ready fusibility; 100 grm. portions were cautiously melted on the sand bath. The loss was 1.25 to 1.50 per cent. The very fair agreement between results and theory shows that melting rosin and shellac together at moderate temperatures has no effect on the iodine absorption.

SERIES I.—Button Lac 22.9. Dark Rosin 178.

	Iodine Number.	Per cent. Rosin Found.
10 per cent. rosin ..	40.8	11.5
20 " " " " " "	56.7	21.8
30 " " " " " "	69.8	30.0

SERIES II.—Button Lac 20.7. Light Rosin 264.3.

	Iodine Number.	Per cent. Rosin Found.
10 per cent. rosin ..	45.1	10.0
20 " " " " " "	65.8	18.5
20 " " " " " "	66.6	18.8

Series III.—Button Lac 16.2. Light Rosin 223.9.

	Iodine Number.	Per cent. Rosin Found.
3 per cent. rosin ..	23.7	3.6
5 " " " " " "	26.2	4.8
10 " " " " " "	38.65	10.8
15 " " " " " "	48.0	15.3

It will be seen that the addition of even 3 per cent. rosin has a marked effect on the iodine value, increasing it from 16.2 to 23.7.

Physical properties.—In the case of the superior grades, SS, VSO, &c., the colour is of some assistance as a guide to purity. When we come to the lower grades, Ralli and TN, it is of uncertain value. With button lacs the colour is no indication whatever of purity. Strength and fracture are also tests of doubtful character. The powdered sample in some grossly adulterated shellacs (about 20 per cent. rosin) will sometimes give evidence of rosin in the odour and stickiness when rubbed between the fingers.

If the sample is prepared for analysis by grinding in a coffee mill, some indications as to purity are obtained in the strong electrical properties shown by the pure shellac, the powder obstinately adhering to the grinding plates and receiver.

Blanching test.—This is a practical test which may be used as a confirmation of the determination of rosin by

the iodine absorption. There is a close connection between the latter and the quantity of bleach required to bleach a shellac properly.

1 oz. (28.35 grms.) of the ground shellac is transferred to a large beaker, and 350 c.c. of water and 5 grms. dry sodium carbonate added. The open beaker is heated on the water bath with frequent stirring until solution of the shellac is complete. For comparative purposes a standard sample of pure shellac (*i.e.*, one with an iodine value of 18 or less) is treated in the same way. The beaker is removed from the bath and the odour of the contents noted. The characteristic smell of rosin is noticeable to most observers with shellacs carrying 10 per cent. rosin or more. With experience as little as 5 per cent. can be detected in this way.

Shellacs containing 10 per cent. or over generally show a flocculent separation. On continued heating this will often collect on the surface in a sticky mass enclosing some shellac. This shows unmistakable properties of rosin. Such a separation from a poor TN showed an absorption of 80 per cent. With pure shellacs the solution is clear, except for the semi-transparent minute particles of undissolved shellac wax.

The solution is allowed to stand for fifteen minutes and decanted through a fine sieve from the sediment of sand, orpiment, &c. The amount of residue in the beaker will give a fair idea of the quantity of mineral matter present. It may be washed by decantation, rinsed into a platinum dish, dried and weighed for a rough determination.

The shellac solution is allowed to cool to about 40° C., and 150 c.c. of sodium hypochlorite solution is added. This should be of such strength that 10 c.c. are equivalent to 32 c.c. of N_{10} sodium arsenite solution. If not of this strength, a volume equivalent to 150 c.c. is used.

The colour due to lac dye is rapidly bleached. A yellowish colour remaining will persist several hours before the final cream colour is obtained; 150 to 175 c.c. will suffice for the bleaching of a pure shellac. Greater amounts of bleach running up to 250 and 300 c.c. will be required if rosin is present. Rosin will absorb much more bleach than shellac and will not bleach as white even with large quantities, a persistent yellow colour remaining with badly adulterated samples.

The solution should be tested for chlorine from time to time with potassium iodide-starch paper. With pure shellac the solution will react for hours, often over night. If much rosin is present, the excess of bleach is rapidly destroyed, sometimes within twenty minutes and additional bleach should be added. It is, of course, important, especially for those lacking experience, to run a test side by side with a shellac of known purity.

After bleaching is complete, the shellac is precipitated with dilute acid, filtered, washed, dried and dissolved in alcohol in the proportion of four pounds to the gallon (20 grms. to 42 c.c.). The colour of the varnish is compared with that prepared from the standard or a good grade of bleached shellac.

Storch-Morawski Reaction.—This well-known test for rosin in fats and oils, depending on the red-violet colour produced on adding a drop of strong sulphuric acid to the solution in acetic anhydride, may be applied successfully to shellac.

A little shellac is dissolved by gently warming with acetic anhydride, and a drop of sulphuric acid added to the cooled solution. A distinct reaction is obtained with 10 per cent. rosin, a doubtful test with 5 per cent.

The following modification renders the test more sensitive. One gram of the sample is treated with 15 c.c. of acetic anhydride. The mixture is gently warmed on the water bath until solution is complete, and cooled by standing in cold water. Rosin remains in solution. The greater part of the shellac separates as a gelatinous mass, which is filtered off. In this way the rosin is concentrated in the filtrate. The test-tube is inclined, and a couple of drops of strong sulphuric acid allowed to flow down the side, agitating the liquid a little as the acid meets it. A coloration, which soon disappears, is obtained with as little as 2 or 3 per cent. of rosin. A pure shellac gives no coloration if care has been taken to avoid charring.

Bleached Shellac. As is to be expected, bleached shellac will absorb less iodine than the crude. It is less easy to detect intentional adulteration here, as it is generally beyond the power of the bleacher to procure a rosin-free shellac to begin with. Rosin carried through the bleaching process loses materially in iodine value. A light rosin with an iodine number of 230 bleached in the laboratory showed a reduction to 121. Nevertheless, an addition of rosin to the final product may be detected without great difficulty in the higher iodine number and colour reaction with Wisp's solution. A series of American bleached shellacs gave iodine numbers of 9.6, 7.3, 8.9, 9.9, 7.6, 7.0, 6.0, 8.3, 9.6, 19.8, 21.4, 16.3. An extra white sample gave 4.4.

The three samples with high iodine values are either adulterated by the bleacher or made from a crude shellac high in rosin.

A bleached shellac of good colour will generally run about 8. Anything much over 10 would point to sophistication. The determination of the proportion of added rosin could be made by substituting in the formula the values 10 and 228.

Shellac Varnish.—Starting out with an adulterated shellac, the varnish maker, secure in his belief that rosin cannot be detected in the solution, proceeds to a still more rosin. What has been said in regard to adulteration of shellac fades into insignificance in comparison with that practiced in the manufacture of shellac varnishes. Shellac varnishes are sold containing no shellac. "Pure" shellac varnishes, grain alcohol, may be purchased at less than the cost of the alcohol. It is, however, easy to detect adulteration. Those who have ever seen a genuine white shellac varnish freshly prepared (and many users have never seen it) should be able to recognise the presence of rosin by the yellow colour of the false article. The characteristic waxy, streaky appearance on the bottle above the level of the liquid is an evidence of shellac wax, which becomes less and less apparent as the varnish is adulterated with wax-free materials.

Adulterated orange shellac varnishes are not readily identified by the colour. Some substitutes are nothing but a solution of Kauri chips in a mixture of wood alcohol and benzene. Alcohol added to such a mixture produces a precipitate.

Determination of the Strength or Body of Varnishes.—0.75 to 1 gm. of the varnish is weighed into a weighed platinum dish and evaporated on the water bath to constant weight (for about 5 hours). The result is calculated in pounds per gallon. Taking the weight of a gallon (231 cu. in.) of wood alcohol at 60° F. as 6.75 lb., we have:—

Pounds per Gallon corresponding to	Per Cent Dry Resin.
3	30.77
3.5	34.15
4.0	37.20
4.5	40.00
5.0	42.55
5.5	44.90
6.0	47.06
6.5	49.05
7.0	50.91
7.5	52.63
8.0	54.23

Examination of the Solvent.—100 grms. of the varnish is distilled until incipient decomposition, and the distillate again distilled. The boiling point will differentiate between grain and wood alcohol. A test for acetone will distinguish between wood alcohol and Columbian spirit. On dilution with three or four volumes of water, benzene will separate if present.

Detection of Adulterants.—The commonest one met with is rosin. The residue, after drying the varnish in the determination of strength, may be used directly for this test, by solution in 20 c.c. glacial acetic acid. If much rosin is present solution will be easy and rapid. The iodine number is then determined as described.

The residue in the case of white shellac varnishes will, if pure, lie between 10 and 15. With pure orange shellac varnish it should run 20 or under, provided a good grade of crude shellac has been used. If not, it may run as high as 30. Anything much higher than 30 would point to adulteration by the varnish maker.

In calculating the per cent. of rosin in the residue, the values 228 for rosin, 18 for crude, and 10 for bleached shellac may be used. Here, again, it is more likely to be a hard rosin of lower iodine absorption which has been used. We are also confronted by the difficulty that other alcohol-soluble resins, such as Manila copal, gum sandarac, &c., may have been used alone or together with the rosin. We can only figure the adulteration in terms of rosin. Express the result in pounds per gallon.

Gum	Iodine Absorption.
Sandarac	160.6
"	174.8
Spirit Copal	118.0
Kauri	119.5
Acetorides	119.3

These values were determined by the standard method described. Their absorptions are less than that of rosin. They all colour Wijs' solution red-brown, and in some cases produce a turbidity, and, after standing, a precipitate. A study of the iodine absorption of these resins together with an examination of the precipitate as to melting point, &c., might lead to useful results.

It will be seen that here, as well as in the crude shellac, any error will be in the direction of low results. I analysis shows a varnish to consist of 4 lb. of shellac and 1 of some other gum (assumed to be rosin) to the gallon we are certain that there is at least 1 lb. of foreign gum present. A knowledge of the market conditions will generally show whether the analysis is far out of the way.

If much rosin is present, it is not safe to take the residue after evaporation for analysis. A little rosin (iodine value 224.3) was dissolved in alcohol, evaporated on the water bath and heated 5 hours. It then showed a value of 148.2. Similarly, a dark rosin 175.7 fell to 131.

Wood alcohol has some effect on Wijs' solution. 20 c.c. Wijs' solution, which required 41.4 c.c. of hypo., fell to 41.0 c.c. after standing for an hour with 1 gm. of wood alcohol, 20 c.c. of acetic acid and 10 c.c. of chloroform. If sufficient varnish be taken to yield 0.2 gm. of residue and enough alcohol is evaporated to leave a pasty residue, this may be dissolved in acetic acid for analysis, and the error due to alcohol will be negligible.

AMERICAN SHELLAC VARNISHES.

Varnish	Pounds per Gallon.	Iodine Number of Residue.	Solvent.
Substitute	3.75	136.1	Benzine and Wood Alcohol.

Of the above only Nos. 14, 16, 18 and 19 are pure. A genuine shellac varnish is rarely met with.

Colorimetric Test for Adulterants in Shellac Varnish.—5 c.c. of glacial acetic acid and 5 c.c. of Wijs' solution are added to 5 drops of the varnish. A pure shellac varnish will remain a light yellow with a shade of red. An impure varnish will almost immediately assume a more or less deep reddish-brown colour. This test may be used with both white and orange shellac varnish. A shellac may be tested in the same way by first dissolving in alcohol in the proportion of 4 lb. to the gallon.

In conclusion, I wish to express my thanks to my assistant, Mr. F. S. White, for the careful way in which he has carried out the experimental work in connection with this paper.

NOTE.—After reading this paper my attention was called to a article by M. Wallerstein, "Brewers' Varnishes of Commerce, American Brewer, 1902, 1292 to 1296. Four tables are given containing the iodine absorptions, ester, saponification and acid values of shellacs, other rosins, artificial mixtures with 25 to 50 per cent. of adulterant and residues from various shellac varnishes. Light coloured crude shellacs are stated to have iodine values of 8 to 10 dark 23 to 26. Neither Parry nor the author found any such gap between light and dark coloured pure shellacs. Wallerstein's dark samples were probably adulterated. The dark coloured garnet shellacs are admittedly adulterated with 6 to 10 per cent. resin and are largely used in brewers' varnishes. The only hint given as to the method employed is the statement that "the quantity of iodine which the unsaturated acid of shellac dissolved in alcohol is capable of absorbing is the iodine equivalent." The objection made to Parry's paper can be made here. With Hübl, modifié Hübl, Wijs and Hanus' solutions all in the field, the time has passed when no description or only a loose description of the method employed can be given.

DISCUSSION.

Dr. WALLERSTEIN said he was very much interested in the paper, especially as his experiments were in the lines of some investigations which he carried out about three years ago. The results of these experiments were compiled in a paper read before the United States Brewmasters' Convention, November, 1902, and which appears in the various brewers' journals ("American Brewer," "Brewers' Journal," "Western Brewer," and "Brewers' Review"). Shellac varnishes were used extensively in breweries where the large fermenting casks were coated in order to protect the beer from coming in contact with the wood. It was of the greatest importance for the purity of the beer that the coating should be resistant and not affected by the liquid. Many brewers have experienced that, notwithstanding the greatest care in varnishing was taken, the result had been disappointing. It was especially noted that the coating turned white as soon as the tubs were filled with beer. This phenomenon had been generally attributed to the improper application of the varnish. As, however, this whitening of the tub often appeared, and even in cases where the greatest pains were taken in applying the varnish, and as this phenomenon only appeared with certain varnishes, it seemed that the quality of the varnish and not the method of applying it was at fault. The various varnishes of commerce were, therefore, examined. A large number of samples of pure shellac and also a variety of rosin and gums (Manila, Kauri, Copal) were obtained and their properties, their solvng agents, and especially the iodine saponification, acid and ester values were determined. Based upon the results, he had been able to point out that pure shellac could be identified by its iodine, saponification, ester and acid values, and that the presence of adulterations could even be quantitatively determined. The brewers' varnishes of commerce were found to be greatly adulterated: in fact, some samples did not contain any shellac at all. He had since then often had the opportunity to prove the correctness of these investigations, and had always been in a position, on the strength of chemical analyses, to judge the quality and purity of the varnishes.

Mr. MAXIMILIAN TOCH said that the iodine absorption method had been used at their factory for the past two or three years, and they had arrived at the determination of the purity of rosins very much on the lines indicated by Dr. Langmuir. In the laboratory of their factory they had adopted both the Hanus and the Hübl methods but had lately discarded the Hübl for the Hanus method.

They had employed several methods for removing the wax contained in shellac. The first and simplest was to centrifuge the dissolved shellac, and the second method which could be sub-divided into any number of methods was the addition of lead or a zinc salt insoluble in water (such as zinc oxide, lead oxide, or lead carbonate) and shaking this into the dissolved shellac; by gravity the wax was carried to the bottom, and the clear shellac solution remained on top.

It appeared to him from the figures which Dr. Langmuir had obtained, that the figures that they obtained at their laboratory for the iodine absorption of shellacs were comparatively lower, and he therefore suggested that a uniform method should be adopted for the determination of rosin in shellac, and that all those who were interested

in organic work of this kind should utilize the same methods, the same reagents, and the same standards.

It was a peculiar fact that in 1904 all the shellacs they had received from India, excepting the very dearest grades, were much inferior to those of 1903 and 1902. It might be possible that there was a climatic condition that affected the quality of shellac, as might occur, for instance, in linseed, or wheat, or any indigenous product. He understood that there had been a famine in India, and that conditions had been generally very poor, but that, of course, would not account for any admixture or adulteration of rosin with the shellac in a dry state. In their laboratory they had attempted to standardise and determine the peculiar reactions of all other varnish resins with a considerable degree of success.

Mr. LANGMUIR, in reply, said that he had examined all the standard periodicals in his review of the literature, but it had not occurred to him to look through the brewers' publication. He reiterated the statement that the colour was a poor guide to quality. Admitting that a shellac handler of long experience could recognise a bad shellac, he would have no idea of the proportion of rosin present. The method described was offered to chemists in order that without any special experience they would be able to pass on a shellac, and would be placed in a position to make a definite statement as to the rosin present so that a claim could be made. He recommended the colorimetric test with Wijs' solution as being one which could be used by the layman as well as the chemist. It was simple and reliable, and particularly useful in testing shellac varnish.

A NEW CAUSTIC SODA PROCESS.

BY HANS A. FRASCH.

In course of investigations made by me some years ago for the Nickel Copper Company of Ontario for the purpose of evolving a practical chemical method for the separation of nickel from copper and other metals, I found that nickel and cobalt could be readily separated from copper by ammoniating a solution of these metals and precipitating the nickel and cobalt in form of nickel- and cobalt-ammonium chloride, by the addition of sodium chloride to the ammoniated solution, the copper remaining in solution (U.S. Patent 669,899). By these means I succeeded in reducing the nickel contents of solutions containing 125 gm. Ni to 0.05 gm. pr. litre. The nickel salt thereby obtained contains six equivalents of ammonia of which two appear to exist in form of chloride; it corresponds to the formula $\text{Ni}(\text{NH}_3)_2\text{Cl}_2 \cdot 4\text{NH}_3$. I then found that nickel hydroxide in presence of ammonia will react upon sodium or potassium chloride, resulting in nickel ammonium chloride and caustic alkali (U.S. Pats. Nos. 688,463, 697,465 and others). Thus, if ammoniated salt brine is treated with nickel hydroxide, the result is nickel ammonium chloride and caustic soda solution. The former, being insoluble in the caustic liquor, is separated by filtration, washed with ammoniated salt brine and subjected to distillation, whereby the ammonia and nickel hydroxide are recovered and returned to the process, while the caustic soda solution is concentrated in the ordinary manner. The amount of nickel hydroxide required is about 80 per cent. of the amount of salt to be converted, but differs in proportion to the amount of water which may be present in the hydrate. If the hydroxide recovered in the process contains 60 per cent. of nickel hydroxide, 200 grms. per litre of ammoniated salt brine yields a 10 per cent. caustic soda solution, converting about 73 per cent. of the sodium chloride contained in the brine. The reaction requires about an hour. What ammonia and unconverted salt the caustic liquor may contain is recovered during the concentration of the liquor. If the process, and particularly the recovery of the nickel oxide is properly conducted, complete conversion of the salt in theoretical quantities may be obtained.

As the nickel ammonium chloride is easily decomposed by water to nickel hydroxide and ammonium chloride, it is important—if high conversion and concentrated caustic liquor is desired—that any excess of water in

the process is avoided, and the conversion should therefore be conducted rather in presence of an excess of salt, so that always a sufficient amount of salt is present to keep the brine saturated as the ammonia is abstracted from it. Besides, an excess of salt forms a good filtering medium after conversion is completed, so that the reaction can be conducted in the same vessel which served for the conversion. The presence of an excess of water is detrimental during the recovery of the nickel oxide, resulting in low per cent., and slow acting, oxide.

The nickel oxide and ammonia are best recovered from the nickel ammonium chloride by distillation in a calcium chloride solution which has been saturated with salt, or in saturated salt brine (U.S. Patent 763,053). A solution of a specific gravity of 1.250 (about 33 per cent. calcium chloride saturated with salt) gives a highly concentrated nickel hydroxide. This solution may in course of the process be brought to a spec. gravity of 1.400 and higher before the calcium chloride liquor is finally discharged. If the nickel ammonium chloride is suspended in such a solution in proportion of 100–500 grms. pr. litre and subjected to distillation, the ammonia in excess of what is bound in the form of chloride is speedily expelled and the nickel oxide more or less hydrated is recovered in coarse form so that it can be readily separated from the calcium chloride solution. It is not necessary to continue distillation until the last of the nickel is precipitated; in fact, it appears more economical to leave a small percentage of the nickel in solution, since the calcium liquor is used over again and only a part of it is removed for the final recovery of the ammonia and nickel it may yet contain in form of chloride.

The ammonium and calcium chloride liquor still containing nickel in solution, after decanting or filtering from the nickel oxide precipitate, is treated with ammonia to convert the nickel contained therein again into nickel ammonium chloride; this may be done by the addition of ammoniated salt brine, caustic soda, or calcium oxide, and it is then again subjected to distillation. If calcium oxide or caustic soda is used, it is well not to add at one time the total quantity required to convert all the ammonium chloride, since a small amount of caustic soda may always be retained by the nickel ammonium chloride of the succeeding charge. The presence of an excess of ammonium chloride—above the amount normally resulting from the nickel ammonium chloride in process—is advantageous in so far as it is a guard against over-treating with lime and allows the treatment of a larger amount of nickel ammonium chloride in proportion to the quantity of calcium chloride liquor used in the process of distillation. An excess of ammonium chloride, however, in course of the distillation, causes also a larger amount of nickel to go in solution in form of chloride, diminishing the quantity of nickel oxide obtainable by distillation before the addition of lime, and this may become troublesome, as, during treatment with calcium oxide, the nickel remaining in solution with the calcium liquor may precipitate before filtration is possible, because the solubility of nickel ammonium chloride in the calcium liquor diminishes as its content of ammonium chloride decreases. Nickel ammonium chloride is also precipitated if too much calcium oxide is added to the liquor, even if its contents of nickel are normal. The amount of calcium oxide to be added to recover the nickel oxide remaining in solution should therefore be regulated by the amount of ammonium chloride which is advantageously left in the calcium liquor and this should be in proportion to the amount of caustic soda retained by the nickel ammonium chloride, plus possibly a small excess. The impurities contained in the lime are allowed to settle, or the treated liquor is filtered, while yet hot, through sand or salt before it is returned to the distilling apparatus. Finally, a sufficient amount of the calcium chloride liquor is withdrawn and replaced by salt brine to again reduce the specific gravity to the desired degree, and to recover the original volume, to which then again fresh nickel ammonium chloride is added. If, for instance, the original volume consisted of 100 litres of liquor containing 30 kilos. of calcium chloride and the liquor after primary distillation has been treated with 5 kilos. of calcium

it would contain approximately 10 per cent. ammonium chloride, so that 25 litres would have to be removed and replaced with salt brine, or water could have to be added and saturated with salt, to reduce the liquor again to 30 per cent., the surplus being removed, if it were desired to operate with 30 per cent. liquor.

To reduce the amount of waste liquor, it is advisable to recover the 25 per cent. rather than to increase the volume to 30 per cent. If the calcium chloride is allowed to remain in the liquor, its practical limit, not more than about 100 galls. of waste liquor need be produced per ton of caustic.

When the treated waste liquor, nickel if still present is evaporated, and then enough calcium oxide is added to cause the final decomposition of the ammonium chloride and recovery of the ammonia.

At first glance it would seem that a double or triple distillation is required, but this is not the case, since the distillation may be all done in the same apparatus, only, periodically or continuously, a part of the liquid contents of the distilling apparatus is withdrawn from the nickel oxide to be treated with calcium oxide, filtered, and immediately returned to the apparatus; fresh quantities of still liquor being constantly withdrawn, treated and returned to the still, both the nickel and ammonia are eventually entirely removed and recovered. The distillation of the ammonia and recovery of the nickel oxide requires about four hours, so that six operations can be conducted in 24 hours, and as an apparatus of 10,000 gallons capacity should produce four tons of caustic soda at a charge, it would be possible to produce at least 20 tons per day.

To reduce the possibility of loss of nickel and ammonia, conversion and distillation can be conducted in one and the same apparatus, though at the expense of its capacity, since the time occupied for conversion including filtration and washing may be assumed to occupy four hours. In this instance, the apparatus for a daily production of ten tons of caustic soda would consist of a converting and distilling vessel of 10,000 gallons capacity, equipped with reflux condenser, a collecting tank for caustic soda solution equipped with steam coil for recovery of possible excess of ammonia, treating tank for calcium oxide, arranged to serve also for filter, absorber for ammoniated brine, and the ordinary storage tanks, concentrators, and fuse pots. The expenditure in equipment of plant, as well as cost of manufacture by this method, are less than are involved in the manufacture of soda ash by the ammonia process, with the further advantage that consumers may produce their own caustic solutions direct from salt.

duty on "alcohol" (ethyl) is \$2.25 per proof gallon, while that levied on "fusel oil" is $\frac{1}{4}$ of 1 cent. per pound.

It can thus be readily perceived that if merchandise containing excessive quantities of "alcohol" could be "entered" and "passed" as fusel oil, it would prove to be an important factor in the case. In view of the possibility that "fusel oil" of this character might be imported, the Customs authorities caused analyses to be made of numerous samples, with the result that the average amount of alcohol in 50 importations was found to be 5.01 per cent. In four instances the amount exceeded 15 per cent.; the results being 16.38 per cent., 18.91 per cent., 25.60 per cent., and 77.35 per cent. respectively.

There appears to be very little literature relating to fusel oil, particularly as regards this phase of the subject and such methods as have been proposed for the determination of ethyl alcohol in this compound have, upon practical application, failed to yield satisfactory results. The following method is based upon the results of experimental work; and is submitted for the consideration of those who may have occasion to make quantitative determinations of ethyl alcohol in fusel oil.

Mix 20 c.c. of the sample under consideration, 20 c.c. of benzol and 60 c.c. of a saturated sodium chloride solution in a cylindrical graduated separator of about 1 in. diameter (an ordinary burette will answer the purpose and after separation carefully read the volume of the sodium chloride solution (the precipitation of a small amount of sodium chloride which occasionally occurs has been found to cause no appreciable error in the estimation of the volume). Place 50 c.c. of the sodium chloride solution after separation in a distillation flask with 60 c.c. of water, distill 50 c.c., and estimate the alcohol contained therein by specific gravity and temperature.

The percentage of alcohol thus found, multiplied by the number of c.c. of salt solution after separation, will represent the number of c.c. of alcohol contained in the brine, and consequently the number of c.c. which were contained in 20 c.c. of the sample; the product of this result multiplied by 5 will equal the per cent. of ethyl alcohol contained in the sample of fusel oil.

On behalf of this method, it may be stated that it requires no special apparatus, and possesses the additional advantages of simplicity, rapidity and commercial accuracy.

Yorkshire Section.

Meeting held at the Chemists' Club, on Friday, December 16th, 1904.

Meeting held on Tuesday, November 29th, 1904.

MR. CLIFFORD RICHARDSON IN THE CHAIR.

PROF. H. R. PROCTER IN THE CHAIR.

COMMERCIAL FUSEL OIL.

• BY SAMUEL F. BALL.

The constantly increasing demand for fusel oil, the annual consumption of which in the United States may now be estimated at 450,000 gallons, has caused attention to be drawn to its composition; 80 per cent. of the entire quantity consumed is used in the manufacture of amyl acetate, and more than 19 per cent. is refined and placed upon the market as amyl alcohol, or "Refined fusel oil."

From a commercial standpoint the essential ingredient is necessarily the amyl alcohol; but recently a problem has been presented which involves the question of the amount of ethyl alcohol which the oil may contain, and what percentage of the latter would be necessary in order to make a separation and recovery of the ethyl alcohol upon a paying basis.

In addition to the expense of manipulation, an element of primary importance which it is necessary to take into consideration is the United States Tariff. The import

DISCUSSION ON MODERN GAS PRODUCER PLANTS.

Mr. J. W. COBB opened a discussion on "Modern Gas Producers" by giving an account of the Mond Gas Plant and its working.* Mr. Cobb described fully the regenerative working of the plant, by which, while the gas is carefully washed and cooled, the heat taken from it is taken up by the ingoing air and steam. This enables a large excess of steam to be used without unduly lowering the temperature of the producer. The excess of steam greatly facilitates the extraction of the nitrogen of the coal in the form of ammonia, so that in this respect the yield is about four times the amount obtained in any other coal distillation processes. Mr. Cobb also described the Talbot mechanical water-cooled poker, which, by a radial arm fixed on a revolving central shaft, so stirs the coal as to greatly lessen the manual labour required on a gas-producer.

*For further information see papers by H. Humphrey, entitled—
"The Mond Producer Plant," Proc. Inst. Civil. Eng., 1897.
"Power Gas and Large Gas Engines," Proc. Mech. Eng., 1900.

An interesting discussion followed, in which the Chairman; Prof. Thompson, of the Leeds University; Messrs. Davies, Fairley, Murphy, Twynham, Weston and Stoddart took part.

Mr. DAVIES specially referred to the Duff Whitfield process which is now being worked near Darlington.

Obituary.

SIR ISAAC LOWTHIAN BELL, BART.,
LL.D., F.R.S.

ORIGINAL MEMBER OF THE SOCIETY OF CHEMICAL INDUSTRY, AND PRESIDENT IN 1889-1890. FORMERLY PRESIDENT OF THE IRON AND STEEL INSTITUTE, &C.

Isaac Lowthian Bell was born on February 15, 1816, at Newcastle-on-Tyne, his father, Mr. Thomas Bell, being an ironmaster, and his mother, a daughter of Mr. Isaac Lowthian, of Newbiggin, in Cumberland. After attending Edinburgh University and the Sorbonne, he spent some time in travel on the Continent, and then, at the age of 24, entered the Walker ironworks, near Newcastle, in which his father was a partner. There he remained till 1850, when he became connected with the chemical works at Washington, in North Durham. Under his direction these became one of the most important concerns of their kind in the North of England. He greatly enlarged them and also laid down extensive plant for the manufacture of an oxychloride of lead introduced as a substitute for white lead by his father-in-law, Mr. H. L. Pattinson, F.R.S., with whom he was associated in the business at Washington. There, too, was introduced in 1860 almost the first plant in England for the manufacture of aluminium by the Deville sodium process.

Soon after the discovery of the main bed of Cleveland ironstone, near Middlesbrough by John Vaughan in 1850, in conjunction with his brothers, Thomas and John, he started ironworks at Port Clarence, on the north bank of the Tees. A little more than half a century ago the site of Port Clarence was a waste of mud and marsh—in fact, the Tees then flooded ground where iron furnaces now stand. Much land in the estuary has since been reclaimed—largely by means of the “cinder balls” from the furnaces, which were used to build retaining walls—and on a portion of this were placed the iron-smelting works of Bell Brothers, among the largest in the Cleveland district. The firm acquired its own ironstone mines, collieries, and limestone quarries, and when it was found that economy in fuel resulted from increase in the height of blast furnaces, the plant, in view of that fact, was reconstructed. The firm was also among the first in the Cleveland district to take advantage of the saving effected by the use of the waste gases for heating the blast. In the development of the Cleveland iron industry it thus played a very important part, and what has been the extent of that development may be judged from the fact that, whereas the district in 1850 produced less than 25,000 tons of pig iron, at the present time Middlesbrough accounts for about one quarter of the total output of this country. Not only was the firm largely responsible for the surveys which revealed the position and extent of the ironstone beds, but it was active in prosecuting those technical studies by which processes have been devised enabling Cleveland ores to compete as raw material for the production of iron and steel with others possessing greater natural advantages. In regard to steel, the great trouble with

those ores is the high percentage of phosphorus (1.8 to 2.0 per cent.) contained in the east iron which they yield; yet Middlesbrough, largely as a result of experiments carried on under Sir Lowthian Bell's direction, at a cost, it is said of between £10,000 and £50,000, produces steel rails in which this percentage is reduced to 0.07 or less. Middlesbrough steel has also been rendered available for shipbuilding purposes, and as chairman of the company he had, in 1901, the satisfaction of announcing that the product of the Clarence Works fulfilled all the requirements of Lloyd's Registry.

Sir Lowthian Bell had an intimate knowledge, both on the scientific and statistical sides, of the iron and coal deposits of the North of England. When the British Association met at Newcastle in 1863, he contributed a paper on the manufacture of iron in connection with the Northumberland and Durham coalfields, in which he calculated that the supply contained in that coalfield was just about sufficient to melt the Cleveland seam, supposing none of it to be used for any other purpose. His aptitude for statistics was also shown in other ways. In 1870 he wrote a paper, bristling with facts and figures, on the sanitary condition of Newcastle, and more recently he compiled an elaborate account of the iron trade of the United Kingdom, compared with that of the other chief iron-making countries. The establishment of a chemical laboratory in connection with the Clarence works shows how fully he realised the importance of the scientific study of industrial processes, and his own researches on the chemistry of iron and steel, some of which have been translated into French and German, have become classic. Many of the most important of these appeared first in the form of papers read before the Iron and Steel Institute, and a number of them were subsequently collected and published in a thick volume entitled “The Chemical Phenomena of Iron Smelting.” Sir Lowthian was also the author of a book on the “Principles of Iron and Steel Manufacture,” as well as of numerous papers contributed to various scientific societies.

One of the original founders of the Iron and Steel Institute in 1869, he filled the office of president from 1873 to 1875, and in 1874 became the first recipient of the gold medal instituted by Sir Henry Bessemer the year before. An original Member of the Society of Chemical Industry, he was elected President in 1889, and his Presidential Address at Nottingham, at the close of his year of office (1890), was a valuable contribution on “*The Smelting of Iron Ores Chemically Considered*.” Among the learned societies he was a member of the Institution of Civil Engineers and of the Chemical Society, and a past president of the Institution of Mechanical Engineers. In a presidential address to the Institution of Junior Engineers in 1900, he gave a short account of the development of the iron trade, and after claiming that Great Britain had been almost the sole author of the improvements that had raised the industry to its present position, declined to admit that our reduced production was due to any inferiority in methods of manufacture. In 1874, the Royal Society made him one of their number; in 1896, he received the Albert Medal from the Society of Arts. He had also the distinction of being elected an honorary member of the American Philosophical Institution. In the municipal affairs of Newcastle he took a prominent part, having been a member of the Town Council for many years, and having held the mayoralty twice. He was a J.P. and D.L. for the county of Durham, and served as sheriff in 1884. The honour of a baronetcy was conferred on him in 1885, and in 1893 he received the degree of LL.D. from Edinburgh University.

Sir Lowthian married, in 1842, Margaret, the second daughter of Mr. H. L. Pattinson, by whom he had six children. He died on December 20th, at his residence, Rounton Grange, Northallerton, aged 88 years.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English—8s. each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States—1s. each, to the Secretary of the Society.

French—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs-Bourgeois, Paris (3^e).

I.—PLANT, APPARATUS, MACHINERY.

ENGLISH PATENTS.

Furnaces, Impts. in — G. S. Kent, Buffalo, U.S.A. Eng. Pat. 23,981, Oct. 26, 1904.

A COMBUSTION chamber having a domed top and side walls which are inclined together towards their lower ends, is enclosed in a casing. The side walls have upper dead-plate and lower-toothed sections and form the inner walls of the fuel chamber. The outer walls of the latter are formed by grate bars, having also upper dead-plate and lower-toothed sections, situated one set on each side of and parallel to the inclined side walls and supported by lugs from the top of the casing. Below the combustion chamber and forming its support are bridge-bars, spaced apart, and supported on two parallel walls, forming a central ash-pit. By means of gearing, operated from without the furnace, the grate bars can be spaced out so as to leave an opening between their lower ends and the bridge-bars through which the cinders may fall into two outer ash-pits, one on each side of the central ash-pit. There is also a crushing and agitating device, operated from without, and working in the spaces between the bars on each side. The whole is enclosed in a suitable casing with openings and covers in the top for the introduction of the fuel and admission of air.

Superheated Steam; Production and Manner of Using — Prince C. de Loewenstein, Arles sur Rhône, France. Eng. Pat. 26,177, Nov. 30, 1903.

THE process claimed, consists: (1) in bringing a certain quantity of saturated steam, contained in a closed vessel, into the superheater; (2) in returning this steam, when superheated to the boiler either totally or after having used a portion of it in a motor; (3) in returning the exhaust steam from the motor as steam to the boiler, making use only of the difference of tension between the superheated and saturated steam.

The apparatus for carrying out the above process consists of a rotating drum divided into a number of compartments by longitudinal partitions, and mounted on supports by means of pivots at each end. The inlet and outlet channels of each compartment are bored through the pivots which thus act as cocks to open and close the steam-pipes which are connected to the bearings in which the pivots work. Two pipes, one from each end of the compartment lead to the boiler, a fan being interposed in one of them to assist the circulation of the steam. Two other pipes and a fan similarly make connection with the superheater, whilst another pipe communicates with the motor. When the drum rotates, each compartment in succession passes first in front of the ducts leading to the boiler and is filled with saturated steam, it is next in communication with the superheater, then with the motor, and lastly with the boiler again, the steam being returned thereto. A modification is claimed in which the steam is taken directly from the superheater to the motor.—W. H. C.

UNITED STATES PATENTS.

Filter-Press. E. Hatschek, New York. Assignor to Niles-Cement-Pond Co., Jersey City, N.J. U.S. Pat. 776,024, Nov. 29, 1904.

THE plates of the press are formed of sheet metal panels, with vertical corrugations, held in a frame. The latter is made in two parts, one forming three sides of a rectangular box, to which the other part, forming the fourth side, is bolted. A groove is formed round the inner edge of the frame to receive the corrugated plate, and is connected to an outlet formed in the lower side. The filter-cloth is held in position round the central feed opening by means of a screw-clamp or "bushing," having flanges with inner corrugated surfaces, which fit into the corrugations on either side of the "panel." The flanges are also provided with prongs, which project across the filtering cell, and serve to transmit "deflecting strains" from plate to plate.—W. H. C.

Furnace. W. A. Koenenman, Chicago, Ill. U.S. Pat. 776,185, Nov. 29, 1904.

IN combination with the combustion chamber and ash-pit of the furnace, is interposed a stepped series of perforated coking shelves, with channel spaces between, so that a limited supply of air passes the perforations, to coke the coal on the shelves, whilst through the channel spaces, a comparatively large supply of air passes to promote com-

bustion of the fuel. There is stoking mechanism, comprising a frame having cross extending bars in the planes of the channel spaces, which bars carry a horizontal series of hollow, parallel stoking bars with air-inlets near their forward ends, and air-outlets at their rear ends.—E. S.

Drier [Drying Apparatus]. W. Angus, Montreal, U.S. Pat. 776,581, Dec. 6, 1904.

WITHIN an outer chamber, heated by dry heat, is arranged a rotatable truncated conical cylinder made of wire-cloth, encircled by hoops, the hoops resting on ball-bearings so supported that the lower side of the cylinder is horizontal. The cylinder is rotated by means of a chain passing round a sprocket wheel fixed around the wider end of the cylinder. The material to be dried is fed into the cylinder at the wider end, and leaves it at the truncated end in the dry state.—H. B.

Centrifugal Machine. S. R. Kennedy, Shippensburg, Pa., Assignor to the American Dairy Products and Manufacturing Co., Philadelphia, Pa. U.S. Pat. 776,745, Dec. 6, 1904.

A LAYER of material, such as blotting paper, is placed in the bowl or basket of the machine, to retain fatty matters, and is separated from the bowl by means of an intermediate layer of textile material, held in position by retaining rings. The whole basket of the machine is surrounded by a chamber connected by pipes to a vacuum pump.—W. P. S.

Separator; Water and Gas —. A. T. Newman, Assignor to J. Threlkeld, Greeley, Kans. U.S. Pat. 776,753, Dec. 6, 1904.

THE separator consists of a closed tank, to which the water and gas are admitted; a float in the tank, perforated at the top, and provided with a siphon, the long leg of which depends inside the float, the short leg being outside it; and a water-discharge pipe, the valve of which is connected to the float so as to be controlled by the rise and fall of the latter.—H. B.

FRENCH PATENTS.

Temperature; Process for varying the —, of various Substances. S. Stark. Fr. Pat. 345,724, Aug. 13, 1904.

THE liquid or gas to be cooled, passes through a vessel or a series of tubes made of some porous material, around which a current of air is made to circulate. The liquid diffuses through the sides of the vessel, and produces cold by its vaporisation. A suitable porous material is baked clay, artificial stone, tin plate pierced by fine perforations, felt, or clay with which asbestos has been admixed to increase its porosity and strength.—L. F. G.

II.—FUEL, GAS, LIGHT.

Water-Gas Plants; Working Results from Dellwik —. W. King. J. Gas Lighting, 1904, 88, 839—840.

LEWES' proposal (see this J., 1901, 1095) to utilise "blue water-gas," produced by the Dellwik process, by passing

it through the retorts during carbonisation — now been put into practice on a large scale for a sufficiently long time for a reliable opinion as to its merits to be formed. At Cleethorpes Gas Works the process has been in use for nearly two years. Detailed working results for the past 18 months are quoted, from which it is seen that the average cost of the water-gas in the holder has been 3.50d. per 1000 cb. ft., and the quantity used has been about 22 per cent. of the total make of the mixed gas. With increasing experience of the process, the amount of benzol required for enrichment has steadily fallen from 0.38 gallon per 1000 cb. ft. of water-gas, during July—September, 1903, to 0.0066 gallon per 1000 cb. ft. during July—September, 1904. During the former period the proportion of water-gas in the mixed gas was 12.6 per cent., the illuminating power of the mixed gas was 16.4 candles, and the calorific value 626 B.T.U. gross; whilst during the latter period the proportion was 21.3 per cent., the illuminating power 15.9 candles, and the calorific value 595 B.T.U. gross. Though practically the whole of the enrichment of the water-gas is now derived from the coal-gas product, there has been no decrease in the yield of coal-gas, but an increase of about 100 cb. ft. per ton. Since the adoption of the plant the tar has been rather thicker, and fetches a slightly reduced price. Tests as to the permanency of the benzol enrichment have been carried out by examining the gas at the works, and at the end of the district, about 1½ miles away, and in no case has the difference in illuminating power reached half-a-candle.

Similar working results, obtained at the Rushden and Higham Ferrers Gas Works during the past ten months, are quoted, and they agree substantially with those given at Cleethorpes. The yield of coal-gas per ton of coal, formerly about 11,100 cb. ft., has increased by 500 to 600 cb. ft. per ton, and in this case the benzol used amounts to 0.292 gallon per 1000 cb. ft. of water-gas, the mixed gas averaging 16 candle-power. At the Ilford and Barking Gas Works gratifying results are likewise being obtained with the process, no benzol at all being used at the latter works.—H. B.

Oxygen in Coal-Gas; Automatic Test for —.

Oil Fuel Burners; Impts. in —. G. and T. Wilton, London. Eng. Pat. 22,753, Oct. 21, 1904.

THE burner is constructed as shewn in the figure, which is a sectional plan. The oil is fed from a nozzle placed above the burner into the open cup *b*, provided with an enlargement *b*¹ for convenience of feeding, and is atomised

by the steam from the jet *a*, being at the same time mixed with air drawn through the open cup *b*. The spray is carried forward through the inner tube *c* to the cup *kl*, in which the spiral *h* rotates and imparts to the spray a rotary motion. The tube *c* is surrounded by an outer tube *e*, leaving an annular space *f* between the tubes. A second supply of steam is sent along this annular space *f*, being driven by the contracted orifice *d* around the inner jet. The steam is supplied by the pipe *j*, and is regulated by the valves *m* and *k*. It is stated that the ultimate mixture of oil spray, air and steam, in the inner tube, meeting with the annular jet of steam, gives a large and efficient flame with a small consumption of steam, and one which burns with comparatively little noise. —W. H. C.

Gas or other Gases containing Ammonia and Cyanogen: Treatment of —, for the Extraction of Ammonia and Cyanogen therefrom, and the Partial Regeneration of the Agents Employed in the Extraction. W. Feld, Homburg-on-Rhine, Germany. Eng. Pat. 996, Jan. 14, 1904.

SEE FR. Pat. 341,614 of 1904; this J., 1904, 861. —T. F. B.
Gas Purifiers, Impts. in —. A. J. Boulton, London. From La Comp. pour la Fabrication des Compteurs et Matériel d'Usines à Gaz, Paris. Eng. Pat. 22,815, Oct. 22, 1904.

The purifying material is arranged within the purifier in superposed parallel layers inclined at about 40° from the horizontal, that is, having an inclination approaching that of the natural slope formed by a heap of material in grains or powder. The purifying material rests on boards, instead of grids, and at the inclination adopted has no tendency to slide. The purifiers containing the sloping boards may themselves be inclined at the same angle, to enable the material to be introduced from the top at the back, and to be discharged after use at the bottom, in front of the apparatus. If the purifier vessels are of the ordinary horizontal form, the alternate series of parallel, inclined boards are made to slope from right to left, and left to right respectively, passages being provided for distributing the gas through the layers of material. —H. B.

Carburetted Air; Apparatus for the Production of —. M. L. Godefroy. Fr. Pat. 345,717, April 25, 1904.

An air-compressor supplies air to two carburetters, one of which contains a very volatile combustible such as gasoline, whilst the other contains a less volatile liquid, such as alcohol. The second carburettor may be dispensed with and replaced by a simple pipe. The two streams of carburetted air (or, alternatively, the stream of carburetted air and that of ordinary air) are led into a regulating valve which admits them, in any desired proportions, into a pipe leading to the gasholder. The latter is an ordinary floating bell, which is connected by means of levers to a stop, acting upon the air-compressor, so that the compressor ceases to work when the gas-holder is full, and re-starts when it is empty. —H. B.

Gas; Process and Apparatus for Producing a Combustible — by means of Liquid Hydrocarbons. F. Cotton. Fr. Pat. 345,933, Aug. 30, 1904.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

Masut [Petroleum Residue]; Use of —, for Fuel in Iron and Steel Works. F. Heck, Stahl u. Eisen, 1904, 24, 1430—1435.

MASUT or astatki has the following average composition: carbon, 87.5; hydrogen, 11.0; and oxygen, 1.5 per cent. It has the sp. gr., about 0.91; temperature of ignition, about 110° C.; coefficient of expansion, 0.00091; and calorific value, about 10,700 cal. The following methods are employed for the utilisation of masut as fuel:—(1) Gasification, with subsequent mixing of the vapour with air, either compressed or at the atmospheric pressure. (2) Atomisation of the masut by means of the so-called "Forsunka" with: (a) steam, (b) compressed air, or (c) by forcing the masut through a jet under pressure. The author describes, with illustrations, various devices which are in use for burning masut. The production of masut in the Baku district has increased from about 74.2 million poods in 1891 to 140.1 million poods in 1900. In 1903, 287.3 million poods or about 4.7 million tons were produced. —A. S.

ENGLISH PATENT.

Meta-cresol from Crude Cresol; Manufacture of —. E. Schultze and Chem. Fabr. Ladenburg, Ges. m.b. H., Ladenburg, Germany. Eng. Pat. 1881, Jan. 25, 1904.

IV.—COLOURING MATTERS AND DYESTUFFS.

Hydrochloride of Rosaniline; A Colourless —. R. Lambrecht and H. Weil. Ber. 1904, 37, 4326—4327.

If ordinary rosaniline be dissolved in 2 parts of 30 per cent. hydrochloric acid, the liquid sets to a paste of crystals, which, when filtered, washed with hydrochloric acid and dried *in vacuo* over quicklime, become quite colourless. The substance dissolves in cold water with a very pale pink coloration. On warming, the intense red colour of Magenta appears. The analysis of the product

agrees fairly well with the formula $C_{20}H_{21}N_3O \cdot 2HCl \cdot 4H_2O$. New Fuchsine deposits no crystals on treatment in the same way with 2 parts of 30 per cent. hydrochloric acid.—E. F.

Nitramines of the Anthraquinone Series. R. Scholl. Ber. 1904, 37, 4427—4448.

Though it is well-known that mono- and di-alkylated anilines are converted by fuming nitric acid into nitrated nitramines, it has not hitherto been found possible to similarly produce nitramines from primary aromatic amines. On the other hand, the author has produced nitrated nitraminoanthraquinones by treatment of non-alkylated aminoanthraquinones and their substitution products with nitric acid of sp. gr. 1.50—1.52. In this reaction, hydrogen atoms in *o*- and *p*-position to the amino groups are also partially or completely replaced by nitro-groups. The nitro-groups, which are directly bound to nitrogen, can be removed from these compounds by treatment with nitratable substances such as phenols, hydrocarbons and alcohols in absence or presence of acids. The more nitro-groups are present in the nucleus of the nitramine, the more stable are the nitraminic groups. Thus tetra-bromo-1, 5-dinitramino-anthraquinone is denitrated by boiling alcoholic hydrochloric acid, whereas 4, 8-dinitro-2, 6-dibromo-1, 5-dinitraminoanthraquinone and tetra-nitro-1, 5-dinitramino-anthraquinone require more powerful denitrating agents, such as concentrated sulphuric acid together with a little phenol. In place of phenol the denitration can be carried out by means of the non-nitrated aminoanthraquinone, if this has free *o*- and *p*-hydrogen atoms. For instance, in presence of sulphuric acid, the following reaction can be carried out:—

It is therefore probable that the nitration of alkylated anilines and amino-anthraquinones takes place in several stages, the amino-groups being first attacked, and nitro-groups transferred from these to the nucleus. Nitramines from β -aminoanthraquinone give green colorations, those from 1, 5-diaminoanthraquinone and its bromo derivatives purple colorations, with phenol and sulphuric acid.—E. F.

2, 3-Diamino-anthraquinone and Some Azines of the Anthraquinone Series. R. Scholl and F. Kaer. Ber., 1904, 37, 4531—4534.

In a previous communication (this J. 1903, 1240) it was shown that Indanthrene is probably *N*-dihydro-1, 2, 2', 1'-anthraquinone-azine. It is now found that 9', 10'-phenanthro-2, 3-anthraquinone-azine obtained by treating 2, 3-diamino-anthraquinone with phenanthraquinone in glacial acetic acid solution, does not give a blue product as 1, 2, 2', 1'-anthraquinone-azine (the root substance of Indanthrene) does, when warmed with alkaline hydro-sulphite solution, but yields a brown, flocculent, insoluble precipitate, almost devoid of dyeing properties. This is regarded as a confirmation of the 1, 2-position assigned to the azine ring in Indanthrene.—A. S.

ENGLISH PATENTS.

o-Oxyanthraquinones and *o*-Oxyanthraquinone-oxy-sulphoacids [*Anthracene Dye-stuffs*]; *Manufacture of* —. M. Iljinskij, Krefeld, and R. Wedekind & Co., Uerdingen, Germany. Eng. Pat. 25,738, Nov. 25, 1903.

Colouring Matters of the Naphthalene Series; Production of —. J. A. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. Eng. Pat. 2468, Feb. 1, 1904.

DYE-*STUFFS*, yielding shades which become deep blue-black on treatment with bichromate, are obtained by condensing naphthazarin with sulphonic acids of aromatic amines in aqueous solution, in presence of boric acid. The term naphthazarin is here stated to include the ordinary naphthazarin obtainable from 1, 5-dinitronaphthalene, and also the dye-stuff obtained from 1, 8-dinitronaphthalene according to Eng. Pat. 890 of 1900 (this J., 1901, 35). For example, a mixture of 200 parts of a 50 per cent. naphthazarin paste, 100 parts of commercial (80 per cent.) sulphanilic acid, 20 parts of boric acid, and 400 parts of water is stirred for 48 to 72 hours, the temperature being maintained at 25—30° C. When completely soluble in water, the mixture is poured into concentrated sodium chloride solution, and the dye-stuff filtered off.—T. F. B.

Anthracene Series; Manufacture of Colouring Matters of the — [*Anthracene Dye-stuffs*]. J. A. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. Eng. Pat. 4998, Feb. 29, 1904.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

ENGLISH PATENTS.

Indigo Paste for Direct Use in the Fermentation Vat: Preparation of —. J. V. Johnson, London. From the Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. Eng. Pat. 3168, Feb. 8, 1904.

THE use of phenol, salicylic acid, formaldehyde, or a fluoride to prevent the formation of mould or other decomposition of the organic substance used in the preparation of indigo paste for the fermentation vat, hinders the fermentation, and also has a deleterious effect upon the vat. The use of certain alkaline substances, however, is free from these drawbacks. Alkali or alkaline-earth oxides and hydroxides, and alkali carbonates are suitable, caustic lime being found to be the best to use. For instance, a 12 per cent. indigo paste is prepared by stirring 540 parts of water into a mixture of 200 parts of pure indigo, 100 parts of bran, 100 parts of wheat flour, 50 parts of molasses, and 10 parts of lime. —T. F. B.

Dyeing, Bleaching, or Washing Fabrics in the Piece: Machinery used in —. J. Cadgène, Zurich, Switzerland. Eng. Pat. 21,397, Oct. 5, 1904.

TWO metal or wooden rotating cylinders of large diameter are fixed at a short distance apart in the vat, entirely above the level of the liquid. The material is wound on these alternately by means of suitable gearing, and is kept in an approximately horizontal position in the

liquid by means of small guiding rollers, whereby it is claimed that rapid and uniform treatment is obtained, and that a considerable length of material may be treated uniformly at the same time. The machine may be used for washing or similar purposes by lowering the cylinders into the liquid, or by filling the vat with liquid. An arrangement of cylinders is appended by means of which the finished material can be conveniently wrung out as it leaves the bath. —T. F. B.

Waterproofing Textile and other Fabrics, String, Ropes, and the like: Manufacture of Compounds for —, and Apparatus therefor. V. B. Brydon Wright, Grestford; W. K. Poulson, Liverpool; and W. M. Mackintosh, Liverpool. Eng. Pat. 25,000, Nov. 17, 1903.

THE compound is obtained from paraffin wax (60 parts), almadina (or alsadina) gum, or gutta percha (20 parts), resin oil (10 parts), and carnauba wax (10 parts). For special purposes the carnauba wax may be omitted, in which case a sticky compound is obtained. —E. F.

Leather, Leather Cloths, and Animal and Vegetable Fabrics: Manufacture and Waterproofing of —. P. C. D. Castle. Eng. Pat. 2167, Jan. 28, 1904. XIV., page 36.

UNITED STATES PATENT.

Dyeing Machine. J. R. Greenwood, Boothwyn, Pa. U.S. Pat. 776,237, Nov. 29, 1904.

THE combination is claimed of a dye-vat in which is suspended a removable framework having a series of top and bottom rollers, a driving and pressure roller to draw the material to be dyed over the former rollers, guide rollers to pass the material back for successive passages, and guide-plates having offset openings, "whereby adjacent courses of the material may be separated and also guided in parallel alignment." A "double series" of these offset openings is provided in such a way that each series of openings may come opposite the spaces between the openings of the other series. —T. F. B.

FRENCH PATENTS.

Silk: Process and Apparatus for Degumming, Bleaching, and Dyeing —. Soc. Schmid Frères. Fr. Pat. 345,173, July 27, 1904.

SILK yarns are placed in the form of hanks upon reels within a movable chamber, and are there treated with hot soap froth, produced by blowing compressed air into a heated soap bath, above which the chamber is for the time being brought. After the yarns have been thus acted upon for about 35 minutes, the chamber is removed and immersed in water, when about four-fifths of the silk-glue present becomes dissolved. The remainder may be removed from the silk by repeating the operations. Silk waste is spread upon wire-gauze trays, which are put one above another into the chamber, or it is packed into suitable receptacles and attached to an endless chain or to a vertically rotating wheel, and thus treated with the hot froth. To dye the silk, the same process is followed, but a dye-bath is employed in place of the soap bath. —E. B.

Dyeing Fibres and Tissues [Aniline Black]: Process of —. C. E. Wild. Fr. Pat. 345,254, July 30, 1904.

TEXTILE materials composed of cotton, wool, silk, &c., are dyed in Aniline Black according to the following process:—The materials are immersed in a bath of aniline hydrochloride, acetic acid, sodium chlorate, ammonium chloride (about double the proportion of this salt commonly used), copper sulphate, and copper acetate. They are then dried in a current of air heated at a temperature of 43°–55° C., which, after passing through them, is allowed to escape. A current of cold or slightly heated air is then circulated in a closed circuit through them until the development of the black is almost complete. Finally, to complete this, steam is forced through them. The materials, which, it is stated, are not injured by the treatment described, are then passed through a dilute chroming bath at the ordinary temperature, and are washed and dried. —E. B.

Degreasing with Volatile Solvents, and Drying, with Recovery of Solvents used. E. Bataille. Fr. Pat. 345,367, Aug. 3, 1904.

The materials, e.g., garments which are to be "dry-cleaned," are placed in a revolving cylinder contained within a boiler connected by pipes with a heating vessel, a still, a condenser, and a solvent-tank. The boiler is then filled with a solvent either by exhausting the air from it, or by displacing this with the vapour of the solvent, and then admitting the latter. This may be used cold, or it may be heated by means of a steam coil at the bottom of the boiler. After a while, the first charge of solvent is withdrawn to the still, and a second, and, if necessary, a third, &c., charge is admitted and similarly removed. The materials are then dried by passing through them an inert gas, such as carbon dioxide, which is circulated successively through the cylinder, through a condenser, to remove as much as possible of the solvent from the gas, through an apparatus in which it is heated to a temperature of about 50° C., and then again through the cylinder, &c., its return to the cylinder.

The apparatus may also be employed in drying tissues which have been treated with indiarubber solutions, for the purpose of recovering the solvents used.—E. B.

VI.—COLOURING WOOD, PAPER, LEATHER, &c.

Chrome Leather: Dyeing of —, and Storing in the "Crust." M. C. Lamb. J. Soc. Dyers and Colourists, 1904, 20, 268—273.

CHROME leather previous to dyeing requires to be washed to remove soluble salts, and the acidity retained by the leather after tanning neutralised by treatment with a weak alkaline solution; 2½ per cent. of borax (calculated on the weight of the drained goods) or ¾ per cent. of sodium bicarbonate are recommended, the leather being afterwards washed previous to dyeing or fat-liquoring.

In order to increase the affinity of the leather for coal tar dyestuffs, it is treated with a tannin or dyewood decoction. The most common tannin and dyewood extracts employed, and the colours they produce are: logwood (violet purple), fustic (buff yellow), gambier (brownish yellow), palmetto (reddish drab), peachwood (bluish red). The maximum amount of the tannin or dyewood extract is about 2 per cent. calculated on the drained weight of the leather; it is applied to the goods at 60° C. in the drum for 20-30 minutes. Strong solutions of tannin or dyewood extracts have a detrimental effect upon chrome leather, reducing the strength, tightening the grain, and impairing the strength of the fibre. When dyeing with basic dyestuffs, it is customary to fix the tannin by adding tartar emetic to the contents of the drum. The author recommends potassium titanium oxalate, "tannotitanium oxalate" or titanium lactate for this purpose. The yellow titanium tannate produced when tannin extracts have been previously employed, reduces the amount of dye necessary in the dyeing. Logwood and titanium produce a black, peachwood and titanium a reddish-yellow colour. The titanium solutions may be employed after the dyeing when acid dyestuffs are employed.

The dyeing is performed in the drum at 65° C. for three-quarters of an hour, the concentrated dyestuff solution being added whilst the drumming proceeds, the fat-liquor being afterwards added to the waste dye-bath and drumming continued for half an hour longer. The fat-liquor usually has a detrimental effect in stripping or altering the shade of colour owing to the large amount of soap present, and the liquor being alkaline.

The author endeavoured to produce a fat-liquor emulsion without using soap, and finally adopted the plan of treating the leather with a preparatory fat-liquor made by dissolving 5 lb. of sodium alginate and 8 lb. of glucose in 2 gallons of water by boiling, afterwards adding 3 lb. of castor or neatsfoot oil, and continuing the boiling for 10-15

minutes. The mixture, which is sufficient for 200 lb. of "struck-out" leather, is afterwards emulsified with 6 gallons of cold water in which 3 or 4 egg yolks have been mixed. The emulsion is applied in the drum at 75° C. for three-quarters of an hour; the goods are afterwards removed and dried for "crust" stock and wet down by drumming in hot water, when required to be dyed, giving the goods a final fat-liquoring after dyeing, using 3 lb. of sodium alginate, 3 lb. of neatsfoot or castor oil in 6 gallons of water for 200 lb. of leather.

Blacks are usually dyed with logwood and iron, the leather sometimes being coloured on the flesh side with a coal-tar dyestuff, e.g., Methyl Violet, Acid Violet, Methylene Blue, &c., before being passed through a weak solution of a mixture of logwood and fustic extract, followed by a weak solution of "nitrate of iron" or ferrous sulphate. The black may be accentuated by treatment with a solution of a titanium salt, either before or after the application of the iron.

Coal tar blacks are little used on chrome leather, the most useful are Naphthylamine Black, Phenylamine Black, Chrome Leather Black C., Corvoline, &c.

Sulphide dyestuffs have been tried with promising results, the necessary addition of sodium sulphide being made to the fat-liquor used after dyeing; also the alkali blues for blue backing, the dyestuff being added to the borax or sodium bicarbonate solution used for neutralising the acidity of the leather.—M. C. L.

Hair; Dyeing Human — with Paraphenylenediamine and Similar Bases. E. Guesquin. Fr. Pat. 345,257, July 2, 1904.

IN order considerably to reduce the formation of quinone and to render the solutions employed innocuous to the skin, the solution of *p*-phenylenediamine or other similar base which is first applied, and the water subsequently used in washing the dyed hair, are rendered alkaline with sodium bicarbonate, Vichy salts, &c.—E. B.

VII.—ACIDS, ALKALIS, AND SALTS.

Bleaching Powder; Formation and Constitution of —. N. Tarugi. Gaz. chim. ital., 1904, 34 [2], 254—260. Chem. Centr., 1904, 2, 1531.

ACCORDING to Lunge and Schaeppi the most active bleaching powder is obtained by using slaked lime containing 27.8 per cent. of water, and working at a temperature of 30°—50° C. The author finds, however, that the presence of oxygen also has an influence on the reaction. A homogeneous mixture of 28 grms. of pure calcium oxide (free from iron) and 9 grms. of distilled water was exposed to the air for some time, and then gave the reactions characteristic of peroxides (blue coloration with tincture of guaiacum resin, red coloration with ferrous sulphate and potassium thiocyanate, blue coloration with chromic acid and ether). The author's view is that in the slaked lime used for the production of bleaching powder, there is present a small quantity of a peroxide; the chlorine acts in the usual way upon water, with evolution of hydrochloric acid and oxygen, which latter immediately reacts with a fresh quantity of calcium hydroxide, producing hydrated calcium peroxide:—

- (1) $4\text{Cl} + 2\text{H}_2\text{O} = 4\text{HCl} + \text{O}_2$;
- (2) $\text{CaO}_2\cdot\text{H}_2\text{O} + 2\text{HCl} = \text{CaO}_2\cdot\text{Cl}_2 + 2\text{H}_2\text{O}$;
- (3) $\text{CaO}\cdot\text{H}_2\text{O} + \text{O}_2 = \text{CaO}_2\cdot\text{H}_2\text{O}$;
- (4) $\text{CaO}_2\cdot\text{H}_2\text{O} + 2\text{HCl} = \text{CaO}_2\cdot\text{Cl}_2 + 2\text{H}_2\text{O}$.

It is concluded that hypochlorites are chlorides of peroxides, and that a bleaching powder yielding 44.09

or active chlorine corresponds to the formation of $\text{CaO} + \text{H}_2\text{O}$. As a confirmation of this view the author found that bleaching powder converts mercury quantitatively into mercuric chloride, according to the equation:— $\text{CaO}_2\text{Cl}_2 + \text{Hg} = \text{CaO} + \text{HgCl}_2$. A. S.

Nitrates of the Alkali Metals and of Metals of the Alkaline Earths, and their decomposition by Heat. P. C. K. J. Chem. Soc. Proc., 1904, 20, 240–241.

NITRATES of the alkali and alkaline-earth metals are mainly yellow or red. Their solutions, excepting that of sodium nitrate, can be boiled and evaporated to dryness without decomposition or oxidation. Magnesium nitrate separates with $3\text{H}_2\text{O}$, when its solution is evaporated to dryness, and in acid. In the desiccator one mol. of water is lost. Even at 60° , its solution evolves nitric oxide; at 120°C the residue consists of $\text{Mg(NO}_3)_2 \cdot \text{MgO}$. Barium nitrate decomposes below 300° into barium nitrite, barium oxide, nitric oxide, and nitrogen. At higher temperatures, the nitrate thus produced decomposes in the well-known way. A. S.

Springing's Soluble Salts; Solubility in Water of — F. Kohlrausch. Z. physik. Chem., 1904, 50, 355–356.

Salts in Non-aqueous (Acetone and Pyridine) Solutions; Reactions of — A. Naumann. Ber. 1904, 37, 4328–4341; 4609–4614. (See this J., 1904, 1088.)

THE following are soluble in anhydrous acetone:—Aluminium bromide, chloride,* nitrate.* Ammonium bromide, chromate,* trichromate, liborate,* iodide, nitrate, perchlorate, thiocyanate, thiosulphate.* Antimony tribromide, trichloride, tri-iodide. Barium bromide, chlorate,* iodide, nitrate.* Bismuth trichloride, tri-iodide. Bromine. Cadmium bromide, chlorate, chloride,* iodide, nitrate. Cesium nitrate. Calcium bromide, chlorate, chloride,* bichromate, iodide, nitrate. Cerium bromide, chloride, iodide, nitrate. Chromic nitrate. Chromic anhydride. Cobaltous bromide, chloride, iodide, nitrate. Cupric bromide, chlorate, chloride, Didymium nitrate. Erbium nitrate. Ferric chloride,

nitrate, ferrous chloride. Iodine. Lanthanum nitrate. Lead bromide, nitrate. Lithium bromide, chlorate,* chloride, iodide, nitrate. Magnesium bromide, chlorate, chromate, iodide. Mercuric bromide, chloride, iodide.* Palladium chloride. Platinic chloride. Potassium bromide, chlorochromate, ferricyanide, ferrocyanide, iodide, nitrate,* permanganate, mercuric iodide, thiocyanate. Rubidium bromide.* Silver nitrate, nitrite. Sodium bichromate.* Stannic chloride, bromide, stannous chloride, bromide. Strontium chloride,* nitrate.* Sulphur. Thallic chloride, thallous nitrate. Thorium nitrate.* Uranium bromide. Uranyl chloride, iodide, nitrate. Zinc chloride.

The following are insoluble:—Aluminium arsenate, carbide, fluoride, hydroxide, potassium sulphate, oxide, phosphate, silicate, silicofluoride, sulphate, sulphide. Ammonium carbonate, chloride, bichromate, hypophosphite, meta-arsenite, phosphite, pyrophosphate, silicofluoride, sulphate, sulphite. Di-ammonium arsenite and phosphate. Monoammonium carbonate, phosphate, sulphate, sulphite. Triammonium phosphate. Antimony nitrate, oxychloride, oxide, metantimonic acid. Arsenic trioxide. Barium bromate, carbonate, chloride, chromate, ferrate, hydroxide, iodate, nitrite, oxide, peroxide, sulphite, thiosulphate. Beryllium chloride, sulphate. Bismuth chromate, nitrate, oxychloride, oxide, sulphide. Cadmium carbonate, oxide, sulphate, sulphite. Cesium chloride, sulphate. Calcium carbonate, chromate, dithionate, fluoride, hydroxide, oxide, sulphite. Dicalcium phosphate, Tricalcium phosphate. Chromium-ammonium sulphate. Chromic chloride, fluoride, hydroxide, oxide, phosphate, sulphate. Cupric carbonate, chromate, fluoride, oxide, sulphate, sulphide, cuprous bromide, chloride, iodide, sulphide. Didymium carbonate, oxide, sulphate, sulphite. Ferroso-ferric oxide, sodium-ferric pyrophosphate, ferric oxide, phosphate, sulphate, ferrous phosphate, sulphate. Lanthanum carbonate, chloride, oxide, sulphate. Lead chloride, chromate, basic chromate, fluoride, hydroxide, oxide, peroxide, red-lead, lead iodide, pyrophosphate, silicate, silicofluoride, sulphate. Lithium carbonate, fluoride, hydroxide, metaborate, pyroborate, phosphate, silicofluoride, sulphate. Magnesium carbonate, hydroxide, oxide, sulphate. Manganese dioxide, sesquioxide, -ammonium phosphate, manganous fluoride, pyrophosphate, sulphate, sulphide, sulphite. Mercuric chromate, oxide, sulphate, sulphide. Mercurous bromide, chloride, chromate. Nickelous chloride, sulphate. Phosphorus pentoxide. Potassium bromate, carbonate, chlorate, chloride, chromate, bichromate, hydroxide, nitrite, pyroantimonate, stannate, sulphate, sulphide. Rubidium chloride, sulphate. Silica. Silver bromide, carbonate, chloride, iodide, oxide, phosphate, pyrophosphate, sulphate sulphide, disulphide. Sodium carbonate, chloride, chromate, hydroxide, stannate, sulphate. Stannic sulphide, stannous oxide, sulphate, sulphide. Strontium carbonate, hydroxide, metaborate, oxide, peroxide, sulphate, sulphide. Thallous bromide, carbonate, chloride, iodide, sulphide. Zinc carbonate, chromate, oxide, sulphate.

Cupric chloride: The saturated solution has a sp. gr. of 0.8154, and contains 1 gm. in 34.7 grms. of acetone. It reacts completely with stannous chloride, giving a precipitate of cuprous chloride. With soluble bromides it forms cupric bromide, which partially dissociates giving insoluble cuprous bromide and bromine. With iodides, it forms insoluble cuprous iodide and iodine. It absorbs ammonia gas, forming the insoluble compound, $\text{CuCl}_2 \cdot 2\text{NH}_3$. It absorbs hydrochloric acid gas, forming a solution, probably of a readily decomposable addition-compound.

Cupric bromide: The solution slowly dissociates (see above). With mercuric chloride, double decomposition occurs, but no precipitation.

Cuprous chloride, suspended in acetone, is converted by chlorine gas into cupric chloride, which dissolves. Bromine gives a mixture of cupric chloride and bromide. Iodine forms cupric chloride and cuprous iodide.

Mercurous chloride, suspended in acetone, forms with chlorine, bromine and iodine, the corresponding mercuric salts, along with mercuric chloride.

Bismuth trichloride: The saturated solution has the sp. gr. 0.9194, and contains 1 gm. in 5.59 grms. of acetone. It is completely precipitated by ammonia gas, forming

* Soluble with difficulty.

a mixture of the compounds $\text{BiCl}_3 \cdot 2\text{NH}_3$ and $\text{BiCl}_3 \cdot 3\text{NH}_3$. With potassium iodide, potassium chloride is precipitated, and a dark-red solution of bismuth iodide formed. With silver nitrate, complete double decomposition occurs, and precipitation of the whole. Hydrogen sulphide precipitates bismuth sulphide.

Antimony trichloride: Very soluble, 1 grm. dissolves in 0.186 grm. of acetone, sp. gr. of solution 2.216. The solution is precipitated by ammonia gas, the compound $\text{SbCl}_3 \cdot 3\text{NH}_3$ being deposited. With potassium iodide and silver nitrate the reactions are the same as with bismuth trichloride. Hydrogen sulphide gives no precipitate.

Ferric chloride: 1 grm. dissolves in 1.59 grms. of acetone; sp. gr. of solution 1.160. The solution is completely reduced by stannous chloride. With potassium iodide it forms ferrous iodide and potassium chloride, which precipitates, the liberated iodine combining with excess of potassium iodide. Silver nitrate precipitates silver chloride. Hydrogen sulphide partially reduces it to ferrous salt with separation of sulphur.

Cobaltous chloride: 1 grm. dissolves in 36.4 grms. of acetone; sp. gr. of solution 0.825. With ammonia, the solution forms blue $\text{CoCl}_2 \cdot 2\text{NH}_3$, changing with excess to red $\text{CoCl}_2 \cdot 6\text{NH}_3$. Silver nitrate precipitates silver chloride. Potassium thiocyanate forms a deep blue solution of cobaltous thiocyanate, and precipitates potassium chloride.

Mercuric chloride: 1 grm. dissolves in 0.7 grm. of acetone; sp. gr. of solution 1.956. Ammonia precipitates $\text{HgCl}_2 \cdot 2\text{NH}_3$. Hydrogen sulphide precipitates $\text{HgCl}_2 \cdot 2\text{HgS}$. Stannous chloride precipitates mercurous chloride, which is not reduced to mercury by excess. Cadmium iodide precipitates a mixture of cadmium chloride and mercuric iodide. Bismuth iodide precipitates mercuric iodide. Cupric bromide precipitates cuprous chloride, chlorine being liberated. Potassium or ammonium thiocyanate precipitates the corresponding chloride. Silver nitrate precipitates silver chloride.

Stannous chloride: 1 grm. dissolves in 1.8 grms. of acetone; sp. gr. of solution 1.6. Ammonia precipitates $\text{SnCl}_2 \cdot 4\text{NH}_3$. Hydrogen sulphide precipitates stannous sulphide. Silver nitrate is not reduced, but precipitates silver chloride. Barium iodide precipitates barium chloride. Cupric chloride or bromide forms cuprous chloride, and stannic chloride or bromide. Chlorine, bromine, and iodine form the stannic halides.

Cadmium bromide: 1 grm. dissolves in 64.5 grms. of acetone; sp. gr. of solution 0.8073. Ammonia precipitates $\text{CdBr}_2 \cdot 2\text{NH}_3$. Hydrogen sulphide precipitates cadmium sulphide, which slowly redissolves as excess of the gas is led in. Silver nitrate precipitates silver bromide. Mercuric chloride precipitates cadmium chloride. Chlorine precipitates cadmium chloride, and liberates bromine.

Cadmium iodide: 1 grm. dissolves in 4 grms. of acetone; sp. gr. of solution 0.994. Ammonia precipitates $\text{CdI}_2 \cdot 2\text{NH}_3$. Hydrogen sulphide precipitates $\text{CdI}_2 \cdot 2\text{CdS}$. Silver nitrate precipitates silver iodide.

Zinc chloride: 1 grm. dissolves in 2.3 grms. of acetone; sp. gr. of solution 1.14. Ammonia precipitates $\text{ZnCl}_2 \cdot 2\text{NH}_3$. Hydrogen sulphide causes a white turbidity which disappears as more gas is led in. Silver nitrate precipitates silver chloride. Alkali thiocyanates behave as with mercuric chloride. Finely powdered potassium chloride shaken with the solution dissolves; the filtered liquid, evaporated, gives crystals of $\text{ZnCl}_2 \cdot 2\text{KCl}$.

Silver Nitrate: 1 grm. dissolves in 227 grms. of acetone; sp. gr. of solution 0.798. Hydrogen sulphide precipitates silver sulphide. A solution of roll sulphur in acetone, heated with the solution for 2 hours under a reflux condenser, gives a dark-brown powder of the composition Ag_2S_2 . Ammonia precipitates $\text{AgNO}_3 \cdot 2\text{NH}_3$. Potassium thiocyanate precipitates silver thiocyanate and potassium nitrate; excess of potassium thiocyanate redissolves the former. Ammonium thiocyanate reacts similarly, but the ammonium nitrate remains in solution. Hydrochloric, hydrobromic, and hydriodic acids precipitate the corresponding halides, the two last redissolving in excess of the acid.

The following are soluble in pyridine (those marked with an asterisk sparingly so):—Aluminium chloride,* iodide,* thiocyanate. Barium bromide,* chloride,

iodide. Bismuth trichloride. Cadmium bromide,* iodide.* Calcium bromide, chloride, nitrate. Cerium bromide, chloride. Chromic anhydride. Cobalt bromide, iodide, nitrate.* Cupric bromide, chloride, cyanide,* fluoride, cuprous bromide, chloride, ferrous chloride, ferrous chloride. Gold trichloride. Lanthanum chloride. Lead bromide, chloride, iodide,* nitrate. Lithium bromide, chloride, iodide, nitrate. Magnesium bromide, chloride, iodide. Manganese chloride. Mercuric bromide, chloride, cyanide, iodide, nitrate.* Nickel chloride,* nitrate.* Palladium chloride,* nitrate.* Platinum chloride. Potassium chloride,* cyanide,* iodide,* mercury iodide, permanganate, thiocyanate. Silver bromide, chloride, cyanide, nitrate, nitrite, sulphate, thiocyanate. Sodium bromide, iodide, nitrite. Stannic chloride, stannous bromide, chloride. Strontium chloride. Sulphur. Uranium bromide. Uranyl chloride, iodide, nitrate. Zinc bromide, chloride. Insoluble are:—Aluminium fluoride, nitrate, phosphate, silicate, sulphate. Ammonium carbonate, chloride, chloroplatinate, metarsenate, pyroborate, pyrophosphate, silicofluoride, sulphate, sulphite, thiosulphate. Monammonium carbonate, hypophosphite, phosphate, sulphate, sulphite. Triammonium phosphate. Barium bromate, carbonate, chlorate, chromate, cyanide, iodide, phosphate, sulphate, sulphide, sulphite. Beryllium chloride, sulphate. Cadmium chloride, nitrate, sulphate. Cesium chloride, nitrate, sulphate. Calcium carbonate, sulphate. Dicalcium phosphate, tricalcium phosphate. Chromium carbonate, chloride, fluoride, phosphate, sulphate. Cobaltic arsenate, phosphate, sulphate. Cobaltous carbonate. Cupric arsenate, arsenite, carbonate, nitrate, silicate, silicofluoride, sulphate, sulphide. Erbium sulphate. Ferric phosphate, sulphate. Ferrous phosphate, sulphate, sulphide. Lanthanum carbonate, sulphate. Lead cyanide, fluoride, phosphate, sulphate. Lithium arsenate, carbonate, fluoride, hydroxide, iodate, metaborate, pyroborate, silicate, silicofluoride, sulphate. Magnesium carbonate, sulphate. Manganous carbonate, silicate, sulphate. Mercuric chromate, sulphate, sulphite. Nickel phosphate, sulphate. Potassium bromate, bromide, carbonate, chromate, dichromate, ferriocyanide, ferrocyanide, hydroxide, iodate, nitrate, perchlorate, pyroantimonate, sulphate. Rubidium bromide, chloride, iodide, nitrate, sulphate. Silver arsenite, carbonate, iodate, metaborate, phosphate. Sodium bicarbonate, bisulphate, bisulphite, bromate, carbonate, chlorate, chloride, metaborate, pyroborate, sulphate, sulphite. Stannic sulphide. Stannous sulphide. Strontium carbonate, metaborate, sulphate. Thallium bromide, carbonate, chloride, iodide. Zinc carbonate, cyanide, sulphate, sulphide.

Mercuric chloride: Great heat is evolved on mixing this salt with pyridine, and on cooling, the excess of the salt crystallises out as the compound $\text{HgCl}_2 \cdot \text{C}_5\text{H}_5\text{N}$. Ammonia gives a white precipitate of $\text{HgCl}_2 \cdot 2\text{NH}_3$. Ammonium thiocyanate gives a precipitate of ammonium chloride. Hydrogen sulphide throws down black mercuric sulphide, which in presence of excess of hydrogen sulphide rapidly turns red. In presence of sulphur in the pyridine solution (which itself does not react on mercuric chloride), the change from the black to the red form does not occur even with large excess of hydrogen sulphide. Hydrogen sulphide reacts with mercuric cyanide, bromide, or iodide, as with the chloride; but the change to the red form of the sulphide is more rapid and pronounced. Silver sulphate precipitates mercuric sulphate. Stannous chloride precipitates metallic mercury. Mercurous salts in contact with pyridine break up into mercuric salts, and metallic mercury; the finely divided mercury is very active chemically.

Cupric chloride: Reacts with pyridine to form $\text{CuCl}_2 \cdot 2\text{C}_5\text{H}_5\text{N}$, which separates; the bright blue solution contains but little cupric chloride. Hydrogen sulphide throws down cupric sulphide, a little remaining in solution, colouring the solvent brown. Silver sulphate forms very slowly a precipitate of copper sulphate. Nitrates (lead or silver) precipitate copper nitrate. Silver cyanide produces a change of colour, indicating reaction, but no precipitate. Thiocyanates change the colour from blue to green,

indicating the formation of supra-thiocyanate; but there is no precipitate unless the chloride formed is insoluble. Similar remarks apply to bromides and iodides.

Silver nitrate. If a few sulphide precipitates or sulphide, as in aqueous solution. Sulphur, when the warm solutions are mixed, throws down Ag_2S , with considerable evolution of heat. Other silver salts behave similarly towards sulphur. *Potassium thiocyanate* precipitates potassium nitrate. Chlorides, bromides, or iodides give no visible reaction unless the nitrate formed by double decomposition is insoluble.

Silver cyanide behaves similarly in all respects to the nitrate.

Pyridine solutions show the peculiarity, that where they exhibit reactions opposed to those of aqueous solutions: the same substances, these reactions persist in the pyridine sense, even in presence of a considerable amount of water.—J. T. D.

Yellow Arsenic; Preparation of —. A. Stock and W. Siebert. Ber., 1904, 37, 4572—4575.

THE vessel A, which can be immersed in liquid air in G, carries the tube-stopper C, hung to the bottom of which by platinum wires is the small beaker C. Stout copper wires E E convey the current from four accumulators through a cryptol resistance at the lower end of C, by means of which a temperature of about 400°C . can be maintained there. Metallic arsenic (sublimed *in vacuo*) is placed in the small beaker, C is placed in position, the joint made tight with sealing-wax, and the vessel A exhausted by the mercury pump. The whole is cooled by liquid air, and the cryptol heated by the current. The arsenic sublimates, and condenses on the walls entirely as the yellow modification; either like flowers of sulphur or as a transparent yellow coating or lacquer on the glass. Heat rapidly transforms it into the ordinary form; sun-light does so too, though if the temperature be kept low, the transformation effected by light is relatively slow—the transformed outer layers act as screens. The change is accompanied by contraction of volume, and seems to be exothermic. The identity of this yellow arsenic with that obtained by Erdmann and von Unruh by distillation into carbon bisulphide, was established.—J. T. D.

Alkali Nitrites; Improved Method of Manufacturing —. J. Grossmann, Manchester. Eng. Pat. 1452, Jan. 20, 1904.

A MIXTURE of graphite and slaked lime is added in small portions, with stirring, to melted alkali nitrate, which may contain a small proportion of caustic alkali. The mass, after cooling, is lixiviated, the solution is evaporated to dryness, and the dry mixture of nitrite and nitrate is again fused with lime and graphite, the operations being repeated until practically the whole of the nitrate is reduced. For lime, other alkaline-earth oxides or hydroxides may be substituted.—E. S.

Nitrates or Similar Salts; Extraction, or Preparation of — [from "Caliche," &c.]. J. C. W. Stanley, London. Eng. Pat. 4796, Feb. 26, 1904.

FINELY-POWDERED "caliche" ("the earth containing the sodium nitrate, mixed with common salt and mineral matter") is added to hot water, and the mixture is boiled until it attains a boiling point of about 240°F ., and then allowed to settle. After a time, the liquor is run into a heated tank, provided with agitators, from which it is pumped, whilst hot, through a filter-press. The filtrate is passed into V-shaped vessels that can be readily tipped on one side, and crystallisation is promoted by passing cooled air through pipes submerged in the solution. If much sodium chloride is present, this is salted out by boiling the solution, and the magma is filtered hot, the sodium chloride remaining in the filter-press.—E. S.

Sodium Ferrocyanide; Manufacture of —. A. G. Bloxam, London. From Administration der Minen von Buchweiler, Buchweiler, Germany. Eng. Pat. 3349, Feb. 10, 1904.

SEE Fr. Pat. 339,966 of 1904; this J., 1904, 714.—T. F. B.

UNITED STATES PATENTS.

Air; Process of Heating — [Production of Nitrogen Peroxide]. H. Pauling, Brandau, Austria-Hungary. U.S. Pat. 777,485, Dec. 13, 1904.

Cyanides; Process of Making Metallic —. M. Voigt, Charlottenburg, and A. R. Frank, Berlin, Assignors to The Firm Cyanid-Gesellschaft, m.b.H., Berlin. U.S. Pat. 775,953, Nov. 29, 1904.

A CRUDE metallic cyanamide is dissolved, and from the cleared solution the cyanamide is separated, and is heated to its melting point under pressure in presence of carbonaceous substances, powdered fluxes, and of inorganic substances containing the base, the cyanide of which it is desired to produce. (See also Eng. Pat. 16,298 of July 22, 1902; this J., 1903, 554.)—E. S.

Ammonia; Process of Making — [from Cyanamide]. A. Frank, Charlottenburg, Germany. U.S. Pat. 776,314, Nov. 29, 1904.

To obtain ammonia, cyanamide is heated under pressure, in presence of carbon dioxide gas, to not less than 100°C ., with a proportion of water of not less than three molecules to two atoms of the nitrogen present in the cyanamide. Ammonia and a formate are obtained by heating cyanamide with steam in the proportions above stated, to about 300°C .—E. S.

VIII.—GLASS, POTTERY, AND ENAMELS.

ENGLISH PATENTS.

Furnaces or Kilns for Enamelling, Melting, or Baking Metals, Glass, Porcelain, Pottery, and the like; Impts. in —. H. H. Cunynghame, London. Eng. Pat. 26,363. Dec. 2, 1903.

MUFFLE or crucible furnaces are constructed with a thin layer of refractory material forming an inner furnace lining, covered with a comparatively thick outer jacket. The latter is formed of non-conducting materials; such as asbestos, plaster of Paris, or the like cemented together with a solution of sodium silicate or other building material, and applied as a plastic mass to the inner refractory lining.—W. H. C.

Glassware; Method of Manufacturing —. J. L. C. V., F. J., F. L., and P. R. Arbogast, Pittsburg, U.S.A. Eng. Pat. 15,866, July 16, 1904. Under Internat. Conv., July 16, 1903.

SEE U.S. Pat. 756,558 of 1904; this J., 1904, 490.—T. F. B.

Glass; Manufacture of —, and Apparatus therefor. J. Forster, St. Helens. Eng. Pat. 20,444, Sept. 22, 1904.

THIS apparatus for the manufacture of hollow glass articles consists of a rotating vessel of refractory material arranged in a heating vessel, and containing the molten glass. Above this vessel is a blow-pipe, attached to a vertically movable cross-frame; the containing vessel and the blow-pipe are rotated at the same rate. Above the vessel containing molten glass, is a graduated cooling chamber. Cooling air is admitted into an annular space in the wall of the chamber, and becomes heated by the sensible heat of the glass cylinder, and passes then into a lower annular space in the wall, thus forming a graduated series of cylinders or rings of cooling air. In the upper part of the chamber is a coil for the circulation of a cooling fluid. Air is admitted to the blow-pipe from a compressor, in quantities proportional to the size of the cylinder drawn, the compressor being regulated by the vertical movement of the blow-pipe. The lower end of the cylinder is finished by cutting off the air-supply, and tapering off the bottom of the cylinder into a thread which is cut off, and the bottom perforated, re-heated, and rotated to open out into a cylinder. A vertically movable frame, capable of revolving horizontally or vertically, and provided with gripping bands, is provided for the removal of the cylinders.—W. C. H.

Glass; Manufacture of Sheet —, and Apparatus therefor. O. Imray, London. From The Window Glass Machine Co., Pittsburg, Pa. Eng. Pat. 22,065, Oct. 13, 1904.

TO the end of a tank furnace, a small chamber is attached, in which is a pivoted ladle, with a slot in it through which the molten glass flows up to a certain level. By tilting this ladle the required amount of glass flows into a drawing pan, supported on vertical supports, by which it can be raised or lowered horizontally or inclined to allow surplus glass to be run off into a receptacle. Above the drawing pan is a frame carrying a group of drawing baits, whereby a number of sheets can be drawn upwards simultaneously into a chamber with an enclosed atmosphere, the outer sheets preventing the inner ones from warping. The lower ends of the sheets are severed from the mass of glass, and the group of baits with the dependent sheets is moved mechanically from the drawing- to an annealing chamber. The chilling device near the point of drawing consists of two concentric tubes, through the inner of which water is circulated. The drawing chamber has hollow walls and means for leading the heat from below the pan to the walls. The pan is provided with a movable cover, which is allowed to be over the pan during reheating and filling. The sheets are separated from the mass of glass by burning off, and to prevent the heat from the burners affecting the upper part of the sheets, oblong or elliptical water tubes are arranged between the sheets, and can be turned with the longer axes horizontal, to reduce the spaces between the sheets.—W. C. H.

UNITED STATES PATENT

Glass-melting Furnace. W. T. Nicholls, Wel. Ung. W. Va. U.S. Pat. 776,196, Nov. 29, 1904.

THE patent relates to a tank-furnace, through which flames and gases can be passed. Retractory tiles, provided with projecting portions to increase the heating surface, are arranged to float on the surface of the bath of molten glass, and are prevented from floating out of the furnace. The object of the tiles is to protect the glass from the action of the flame, and means are provided for the introduction of raw material to the bath below the level of the tiles. W. C. H.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Fire-Bricks; Refractoriness of Some American —. R. F. Weber. Amer. Inst. Mining Eng., Sept., 1904.

THIS paper contains an account of a series of observations made on 44 samples of American fire-bricks, in order to trace the relation between chemical composition, refractoriness and texture; and also gives a comparison of a number of American and foreign analyses and fire tests. In the literature of the subject, it is pointed out, that though the analytical data are fairly complete, the details of the fire tests are meagre, and cannot be reduced to a comparable basis.

The samples examined were submitted to a partial chemical analysis, and the fusing point determined, in a Deville furnace, by means of Seger cones, observations of the texture of the bricks being also recorded. The partial analysis included the determination of—total silica, alumina, ferric oxide, and titanium oxide; the difference between the aggregate percentages of these components and 100, represents the percentage of alkaline earths and alkalis. The analytical methods used were mainly those suggested by Richardson and Hillebrand for the analysis of cement (this J., 1902, 30), the titanium oxide being determined by Weller's method.

In any brick there is usually a large number of very coarse angular or rounded grains from 1 to 5 mm. in diameter, of flint-clay, quartz, or burnt material, surrounded by a more or less fine-grained matrix, which usually fuses first, and may cause the brick to lose its shape rapidly. The point at which the matrix softened sufficiently to cause the brick to lose its shape was taken as the fusion point.

The influence of texture on fusibility is emphasised from an observation of Ries that the fusibility of almost any of the New Jersey fire-bricks he examined, could be reduced four or five cones by grinding the brick sufficiently fine to pass through a 100-mesh sieve.

Titanium oxide, together with the ferric oxide, alkaline earths and alkalis, is included under the term "sum of the fluxes," since Ries has shown that 2 or 3 per cent. of it added to a high-grade kaolin, will lower the fusion point two or three cones. In many published analyses the amount of titanium oxide is not given, and consequently the alumina content appears too high and the total fluxes too low, by the amount of titanium oxide present.

The table given shows graphically the results of the author's tests. The following salient points may be noted:—In all the bricks fusing above cone No. 30, 55 per cent. of silica is a fairly good mean, and 65 per cent. for bricks fusing below that temperature; hence the silica content is a rough estimate of refractoriness. It should be noted that No. 4 is a silica-brick. The high percentages of total fluxes in samples 10 and 32, show that except for the presence of fluxes, an increase in silica naturally accompanies a decrease in alumina. A fair refractoriness of a brick, in spite of moderately high percentages of silica and total fluxes, may be due to the fact that much of the quartz, which is a powerful fluxing element, is bound up in grains sufficiently coarse to prevent an active fluxing action. Samples Nos. 25 and 40 illustrate this, the latter being fine-grained, while the former contains many flinty

particles 2 to 5 mm. in diameter. A high content of total fluxes does not necessarily indicate a low refractoriness, though a coarse grain may in such cases account for the result. The author concludes that the refractoriness of a fire-brick depends upon the percentages of silica, and total fluxes, and on the coarseness of grain, and that, therefore, except within wide limits, chemical analysis alone is an insufficient guide. In the case of clays, however, the texture may be regarded as practically uniform, and chemical analysis will, therefore, indicate the refractoriness much more closely.

In conclusion, the author gives some published data referring to foreign bricks and clays similar to those he obtained for American bricks, and the results tend to confirm those given above.—W. C. H.

Calcining Furnace [for Gypsum, &c.]. W. A. Koenen, Chicago, Ill. U.S. Pat. 776,186, Nov. 29, 1904.

The furnace is intended for calcining gypsum or the like. The calcining chamber has its feed opening at the upper part and its discharge opening below, so that the gypsum descends by gravity, past the sides of heating

flues crossing the chamber, which, as well as flue-spaces on opposite sides, are closed, so that the products of combustion traversing the flues, do not come in contact with the descending gypsum. Each flue-space communicates at its lower end with the heating medium, and has its outlet towards its upper end, diaphragms in the flue-space operating to direct the hot gases in a zigzag course through the flues and flue-spaces. There are air-supplying and distributing, and vapour-abstracting conduits opening into the chambers, and extending parallel with the flues, and mechanical means for agitating the descending material.—E. S.

Stone; Manufacture of Artificial —. C. Rubitschung, Frankfurt-on-the-Maine, Germany. U.S. Pat. 777,145, Dec. 13, 1904.

FRENCH PATENTS.

Bricks; Process for Covering —, with a *Protective Coating to Prevent Efflorescence and Blackening*. M. Perkiewicz. Third addition, dated Aug. 6, 1904, to Fr. Pat. 330,655, March 27, 1903.

This addition to the original patent (see Eng. Pat. 3760 of 1904; this J., 1904, 662) is for improvements in applying the coating on the belt coming obliquely up or down from the press, or coming from a mouth-piece with inclined edges, or for using the covering, in place of oil, by spreading it on separate moulds, or on the moulding pistons, the moulded articles being able also to be placed on an arrangement which brings them back to receive the coating.—W. C. H.

Floors; Material for Covering —, and *Method of Manufacturing it*. Deutsche Bodenbelag-Ges. Stuttgart, Stegmeyer and Maurer. Fr. Pat. 345,669, Aug. 18, 1904.

The material consists of a thick mixture of coloured casein, nut-galls, animal or vegetable fibres, and a resinous substance finely-divided and dissolved in, say,

turpentine. This mixture is obtained as a pulp in the cold, and may be spread with rollers on a suitable foundation, such as wood, textile fabrics, glass, &c., and solidifies on drying, and can then be worked down with glass-paper, polished and waxed. It gives a floor or wall covering of equal thickness all over the surface, without any joints, and is impermeable, and easily cleaned.—W. C. H.

Cement; Process of Manufacturing Impermeable and Acid-proof —. R. Liebold. Fr. Pat. 345,421, Aug. 8, 1904.

The acid-proof cement is made by moistening 100 kilos of unbroken, calcined cement with a mixture of 300 grms. of Japan wax and 20 grms. of caustic alkali emulsified with 8 litres of boiling water. The product is then dried and finely powdered. (See also Eng. Pat. 4606 of 1904; this J., 1904, 490.)—W. C. H.

X.—METALLURGY.

Steel Worked "in the Blue." ["Blue-shortness."] *Absence of Brittleness in* —. C. Frémont. Comptes rend., 1904, 139, 1032–1033.

It is generally supposed that all irons and steels acquire shortness when subjected to permanent deformation, either by pressure or by shock, whilst at a temperature lying between 200° and 450° C. (Compare Ledebur, this J., 1887, 42.) The author has found that some steels, particularly those used in the construction of certain locomotive boilers, do not become brittle under these conditions, and he concludes that "blue-shortness" is not an absolute property of iron or mild steel, but a defect which may in certain cases be avoided by suitable conditions of manufacture.—H. B.

Chlorination [Gold Extraction]; The New —. W. E. Greenawalt. Eng. and Mining J., 1904, 78, 872–874.

The author discusses the relative costs and advantages of the chlorination and cyanide processes of gold extraction, more particularly with regard to the treatment of Cripple Creek ores. He concludes that with the application of chlorine generated electrolytically from sodium chloride, the cyanide process will no longer be able to compete successfully with chlorination for the treatment of Cripple Creek gold ores. It is estimated that electrolytic chlorine would cost only 15 cents per ton of ore as compared with 75 cents for chlorine obtained from bleaching powder and acid; whilst if plant were provided for recovering and refining the caustic soda produced in the electrolytic process, the value of this product would about cover the total expense of generating the chlorine.—A. S.

Metals; Action of Potassium Cyanide Solution on —. A. Brochet and J. Petit. Bull. Soc. Chim., 1904, 31, 1255–1257.

ALUMINIUM and magnesium are readily attacked by a solution of potassium cyanide in the cold; but of the other metals only copper and zinc cause an appreciable evolution of hydrogen, a double cyanide being formed. In the case of zinc, the action soon stops owing to the formation of the insoluble double cyanide $Zn(CN)_2 \cdot 2KCN$ which protects the metal. At the boiling point the reaction is much accelerated. Certain metals, e.g., cadmium and silver, will dissolve only in the presence of air or oxygen; whilst mercury remains unattacked.

Quantitative experiments show that when a strip of platinum is boiled with potassium cyanide solution, the surface gradually becomes pitted, and there is a decrease in weight. If the metal is then placed in a fresh solution and the boiling repeated, the loss of weight is greater and approximates to 0.030 gm. per sq. dem. per hour.—B. J. S.

Slags; Formation of —, in *Smelting Operations. Constitution of the Slags and their Industrial Application*. Mathesius. Berg- u. Hüttenm. Zeit., 1904, 63, 381–387; Z. angew. Chem., 1904, 17, 1891.

IX dealing with the constitution of slags the work of Ackermann and Vogt on silicates, and of G. Hilgenstock

on phosphate slags (this J., 1886, 606) is reviewed. The technical applications of slags are then discussed, especially the manufacture of "slag-cements" and the use of Thomas slag as a manure. A process (due partly to the author) is described in which granulated blast-furnace slag, sufficiently basic, is treated with exhaust steam which causes it to swell and fall to a soft dry amorphous powder of great fineness, which sets and hardens with water like a cement; the cost of mulling and burning is thereby saved.—F. Dry Separator [for Ores, &c.]. T. A. Edison, Lowelllyn Park, N.J. U.S. Pat. 775,965, Nov. 29, 1904.

A BLAST of air is sent through a tube of substantially uniform cross-sectional area, and having two screen diaphragms, spaced apart, extending across the whole area of the tube. The first of these diaphragms is of coarser mesh than the second, and the space between them serves as a pressure-equalising chamber. The feed hopper, which is situated on the upper side of the tube, immediately after the second screen, delivers a thin, uniform, vertical sheet of pulverulent or granular material, which falls across the whole area of the tube. The material is graded by the air blast, and falls into suitable separate receptacles placed on the lower side of the tube.—W. H. C.

Iron and Steel; Apparatus for the Treatment of Iron and the Manufacture of —. M. Moore and T. J. Heskett. Fr. Pat. 345,599, Aug. 16, 1904.

THE furnace is adapted for the continuous treatment of iron sand or powdered iron ores, which are mechanically delivered into a vertical shaft, set with baffle arrangements, in which the descending ore is met by waste or other heating gases. The ore thus heated is deflected at length into a side chamber, from the bottom of which it is worked by a horizontal screw into the second division of the shaft, also provided with baffles; the ore then descends to a channel leading to the hearth, meeting on its way reducing gases. The hearth, on to which the reduced and heated ore thus descends, may be revolved, or moved upwards or downwards. The upper portions of the shaft, in which the ore is heated, may be replaced by an inclined revolving cylinder. — E. S.

Iron and Steel; Process for Hardening and Cementing Soft —. Soc. Cyanid Gesellschaft. Fr. Pat. 345,642, Aug. 17, 1904.

THE iron or steel article is heated with a cyanamide or with one of its alkali or alkaline earth compounds, with addition of a substance containing carbon, followed by a flux, such as sodium carbonate or chloride, or calcium chloride or fluoride. The mixture of calcium cyanamide with charcoal may be obtained as described in Fr. Pat. 289,826, of June 12, 1899. — E. S.

Calcareous Minerals; Process of Enriching —. E. Ledue and C. Griffiths. Fr. Pat. 339,162, Nov. 12, 1903.

Soldering Paste; Manufacture of —. R. Küpper. Fr. Pat. 345,593, Aug. 13, 1904.

THE soldering paste is composed of a powdered metal or alloy; a soldering agent which does not leave an acid residue, such as ammonium chloride, borax, or soluble glass (alkali silicate), and glycerin or other liquid inert carbon compound, which will not evaporate before the soldering agent, or the metal employed in soldering, fuses. — E. S.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(A.)—ELECTRO-CHEMISTRY.

Hydrogen-Oxygen Cell; Potential of the —. F. J. Brislee. Paper read before the Faraday Society, Nov. 23, 1904.

THE potential of the galvanic cell:

Platinised platinum | N acid | Platinised platinum
charged with hydrogen | | charged with oxygen

on measurement by different experimenters, has been found to lie between 1.076 and 1.14 volts.

It is not at all unlikely that a little persulphuric acid, hydrogen peroxide and ozone may have resulted during the electrolysis, and the investigations here recorded were undertaken with a view to determine the influence of traces of these bodies upon the oxygen potential. Two lines of work were followed:—First, the electrodes were

polarised by electrolysis extending over 2 or 3 days; and second, the electrodes were freed from gases as completely as possible, and then the respective gases were passed through the liquid and the potential was measured from time to time till constant. Thus, two potential limits were obtained—the first, starting from a high potential and gradually falling, and the second rising to a constant value. When the potentials were constant to about 1–2 millivolts, the effect of the addition of the various substances was tried.

The combination $\text{Pt} \begin{smallmatrix} \text{H}_2 \\ \text{N} \\ \text{I} \end{smallmatrix} \text{H}_2\text{SO}_4 / \text{Pt} \begin{smallmatrix} \text{O}_2 \end{smallmatrix}$ was found

to give a potential difference of about 1.082 volts at 18° C. The addition of hydrogen peroxide lowers the oxygen potential, whereas persulphates and ozone raise the oxygen potential and diminish the rate of discharge of oxygen by an electrode supersaturated with oxygen by electrolysis. By employing electrodes of extremely thin platinum deposited upon glass and platinised, the same potential was obtained independently of the method of charging the electrode with oxygen. Such electrodes give a potential in close agreement with that calculated from Hahnoltz's formula. — R. S. H.

Electrolytic Oxidation of Hydrocarbons of the Benzene Series. I. Hydrocarbons containing the Methyl Group. H. D. Law and F. M. Perkin. Paper read before the Faraday Soc., Oct. 25, 1904.

THE authors have investigated the electrolytic oxidation of toluene, *o*-, *m*- and *p*-xylene, mesitylene and pseudocumene, the hydrocarbons being partially dissolved in acetone, with sulphuric acid as electrolyte. It was found that electrolytic oxidation under these conditions is not so energetic or far-reaching as oxidation by chemical reagents. The chief product of the electrolytic oxidation was, in each case, the corresponding mono-aldehyde. In the case of the xylenes, the ortho and para compounds gave higher yields of the corresponding aldehydes than the meta compound, the latter being more readily oxidised to carbon dioxide and water. When three methyl groups are present in the hydrocarbon, they all appear to be more or less attacked, so that by the oxidation of pseudocumene, a mixture of different compounds is produced. Some of the yields of mono-aldehyde obtained were as follows, the percentages being calculated on the weight of the hydrocarbon employed. Benzaldehyde from toluene, about 7 per cent.; *m*-toluic aldehyde from *m*-xylene, 10–15 per cent.; *o*-toluic aldehyde from *o*-xylene, 25–30 per cent.; *p*-toluic aldehyde from *p*-xylene, 25–35 per cent.; aldehydes from pseudocumene, 10–12 per cent.; aldehyde from mesitylene, 10–15 per cent. — A. UNITED STATES PATENT.

Ammonium Formate; [Electrolytic] Process of Manufacturing —. H. Pauling, Brandau, Austria-Hungary. U.S. Pat. 776,543, Dec. 6, 1904.

AMMONIUM formate is produced by subjecting a mixture of hydrogen, nitrogen, carbon monoxide and steam to non-luminous electric discharges, in presence of porous contact substances. — T. F. B.

FRENCH PATENTS.

Electrolytic Process and Apparatus. C. P. TOWNSEND.
Fr. Pat. 345,871, Aug. 26, 1904.

This invention comprises an electrolytic cell divided into two compartments by a permeable cathode of iron wire gauze, and a diaphragm permitting of a limited filtration of the electrolyte. One compartment contains the anode of graphite and the electrolyte, which may be a solution of a salt of an alkali metal, and in the other is a liquid, such as a non-saponifiable oil, which will not mix nor react chemically with the product of electrolysis formed at the cathode. A circulation of the oil is produced by the rising bubbles of hydrogen, and the circulation and the rising bubbles of gas assist in detaching and carrying away the globules of caustic solution from the surface of the cathode. An arrangement is provided in the cathode compartment, whereby the temperature of the oil, and thus the temperature of the electrolyte, may be varied.—B. N.

Oxidising and Reducing Organic Substances; Process for Electrolytically —. Farbwerke vorm. Meister, Lucius und Brüning. Fr. Pat. 345,701, Aug. 19, 1904. Under Internat. Conv., Sept. 12, 1903.

ORGANIC substances can be easily reduced or oxidised electrolytically in presence of small quantities of vanadium compounds. The salts of the oxides V_2O_5 and V_2O_3 are suitable for reducing, whilst V_2O_4 and V_2O_5 are oxidising agents. For example, azobenzene is reduced to benzidine by electrolysis in a 20 per cent. solution of sulphuric acid containing about 2 per cent. of vanadium trioxide; the bath is heated to about 50°C ., and a current density of 100–200 amperes per sq. metre is employed. Anthracene may be oxidised in a 20 per cent. solution of sulphuric acid containing 1 per cent. of vanadic acid, at a temperature of about 80°C ., using lead electrodes; a current density of 300 amperes per sq. metre at 1.6 volts is employed. (Compare U.S. Pats. 729,502 and 742,797 of 1903; this J., 1903, 872 and 1355.)—T. F. B.

Vulcanisation of Rubber; Impts. in [Electrical] Heating Apparatus, especially those used in the —. Electric Moulding and Heating Co. Fr. Pat. 345,606, Aug. 16, 1904. XIII C., page 36.

Steel; Electric Furnace for the Manufacture of —. G. Dary. L'Electricien, 1904, 27, 305. Proc. Inst. Civil Eng., 1904, 158, 37.

THE author gives a description of a new type of Kjellin electric furnace without electrodes. The ore is placed in a circular chamber, around a coil wound with copper wire, and provided with a rectangular laminated core of thin plates of soft iron. On passing an alternating current through the coil, a variable magnetic flux is set up in the core and induces an alternating current in the furnace-charge. The intensity of the current passing through the charge is equal to the number of amperes flowing through the coil multiplied by the number of turns in the coil. A high tension alternator may be used as a direct source of current, and the furnace is therefore specially suitable where water-power is utilised. The system has been under trial in Sweden since 1900, and recent tests are stated to have given good practical results. With a furnace of 1800 kilos. capacity, and an alternator of 165 kilowatts, 4100 kilos. of steel were produced in 24 hours. 1000 kilos. of steel are withdrawn at each cooling, and 800 kilos are always left in the furnace to form a secondary circuit. The cost of production of the steel amounts to 0.015 franc per h.p.-hour. The cost of maintenance of the furnace is very low.—A. S.

Potassium Cyanide; Action of — on Metallic Electrodes. A. Brochet and J. Petit. Bull. Soc. Chim., 1904, 31, 1257–1261.

THE action of potassium cyanide solution on metallic anodes depends largely on the current density used. Copper, cadmium, silver, and within certain limits of C.D., nickel, dissolve quantitatively. Cobalt and mercury dissolve,

but the latter becomes coated with a thin insulating layer, whilst lead, iron and platinum may be considered as insoluble anodes. Silver and cadmium are readily deposited on the cathode, a very small percentage remaining in solution; zinc, copper and nickel, however, are deposited only with difficulty. Iron and cobalt persistently remain in solution. When a current is passed between platinum electrodes, the cathode gradually loses in weight, probably alloying with the alkali metal, and subsequently separating as finely divided platinum. The authors believe these mechanically separated particles to be more attenuated than Bredig's "colloidal platinum," since they dissolve more readily in potassium cyanide solution, and after the current has ceased, the liquid continues to evolve hydrogen for 1.2 hours. The solution of the cathode appears to be greater with barium cyanide.—B. J. S.

Metals; Theory of the Solution of — in Potassium Cyanide, under the Influence of Alternating Currents. A. Brochet and J. Petit. Bull. Soc. Chim., 1904, 31, 1261–1265.

Those metals which are dissolved by potassium cyanide at the anode, using direct current, and quantitatively deposited at once at the cathode, remain unattacked when an alternating current is used. Thus silver is unattacked; cadmium behaves somewhat similarly, whilst copper, nickel, zinc, and cobalt readily dissolve. The action on platinum is, however, entirely dependent on the process of cathode solution described in the preceding abstract, and the metal is rapidly dissolved. Curves are given showing the behaviour of metals under varying frequencies, and of nickel under varying frequency and current density. The authors summarise their results as follows:—

- (1). The alternating current admits of the preparation of different compounds.
- (2). The frequency has an important bearing on the behaviour of the electrodes. (See also page 31.)—B. J. S.

Zinc; Electrolytic Separation of —, from Zinc Chloride in Acetone Solution. H. E. Patten. J. of Phys. Chem., 1904, 8, 483–487. Chem. Centr., 1904, 2, 1532.

THE current-curve corresponding to the separation of zinc with platinum electrodes from a solution of zinc chloride in acetone is shown in Fig. 1. The

Fig. 1.

Fig. 2.

CLAIM is made for a revolving drum provided on its periphery with pockets to receive the liquid soap, and with means for cooling its interior by water, cold air, &c., with or without the addition of an external cooling device. The solidified tablets are removed by hand, or by mechanical

means, such as a series of pistons, the heads of which form the bottoms of the moulds, and as the drum revolves, work upwards and expel the soap. Or the sides of the moulds may be closed by plates in which are openings for the introduction of a rod to expel the bar of soap laterally.—C. A. M.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

(A).—PIGMENTS, PAINTS.

ENGLISH PATENT.

Paints or Pigments; Manufacture of —. M. Hérisson. Paris. Eng. Pat. 2376, Jan. 30, 1904.

SEE FR. Pat. 337,440 of 1903; this J., 1904, 495.—T.F.B.

FRENCH PATENT.

Basic Zinc Carbonate [Pigment]; Manufacture and Application of —. C. J. Barbier. Fr. Pat. 339,151, Nov. 7, 1903.

WATER saturated naturally or artificially with calcium carbonate or carbonic acid is electrolysed with anodes consisting of plates of zinc, and cathodes of any suitable conducting substance such as carbon or a metal. The zinc is converted into a basic carbonate, which, after drying, is used as a pigment in place of white lead. It is said to cover better than the latter, and is non-poisonous.—M. J. S.

(B).—RESINS, VARNISHES.

FRENCH PATENTS.

Amber; Method of Utilising Waste Yellow —. H. Thiemann. Addition dated July 15, 1904, to Fr. Pat. 345,196, July 15, 1904 (this J., 1904, 1226).

THE γ -resin remaining in the insoluble residue obtained by treating waste amber with chloroform, as described in the main patent, is purified by fusion, and is then treated with boiled linseed oil and turpentine to produce a lac or varnish, which is stated to give a harder film than that obtained from amber itself. The proportions specified are 45 parts of boiled linseed oil and 80 parts of turpentine for 75 parts of the γ -resin.—A. S.

Linerusta and Similar Materials; Process and Apparatus for Embossing and Colouring or Painting —. F. Walton. Fr. Pat. 345,848, July 29, 1904.

THE invention has reference to a machine by which the embossing and colouring of linerusta are effected in one operation and continuously. The materials for forming the linerusta are compressed into a sheet of suitable thickness, which is then passed between the embossing cylinders. From these it passes to one or more colouring rollers, each of which applies a different colour. These rollers, which are made of printers' roller composition, are facsimile reproductions of the embossing cylinder, and are obtained by taking a plaster cast of the embossing cylinder, which cast is then used as a mould for the roller composition. Any parts of the colouring rollers which are not to apply paint to the linerusta are cut away, and all the rollers are so geared together that corresponding parts will be applied to the same parts of the sheet of linerusta.—M. J. S.

(C).—INDIA-RUBBER, &c.

Caoutchouc; Pre-existence of —, in the Latex. W. Esch and A. Chwölles. Gummi-Zeit., 1904, 19, 165-166. (See this J., 1903, 1200; 1904, 990, 1036, 1154.)

THE authors review the discussion which has recently taken place as to the form in which caoutchouc is present in the latex, and conclude that it is indisputable that in all the more important rubber-yielding latices there is present not ordinary caoutchouc, but globules of an oily fluid which is converted into caoutchouc by polymerisation.

The substance including the globule, of course, consists, as Weber states, of an albuminoid compound, but the proof of this view is by no means complete. Weber considers that the oily fluid is an olefin, diisoprene, $C_{10}H_{16}$, but the authors incline to Harries' view that it consists of a compound with a tolerably high molecular weight. Weber's argument, based upon the solubility of the oil in ether, is quite invalid since ordinary caoutchouc is soluble to a considerable extent in ether, as has been shown by Fendler (this J., 1904, 1103), and is not completely insoluble as stated by Weber.—A. S.

Mascarenhasia. Rubber Plant of Madagascar. India-Rubber J., 1904, 28, 620.

THE black rubber of Madagascar is obtained from the *Mascarenhasia*, *M. visianthifolia*, *M. aucups* and *M. longifolia*, the pink from the *Landolphia*, and the white from *Euphorbia latifolia*. The three *Mascarenhasia* grow in dry, damp and wet soils respectively. The coagulating medium employed is an aqueous decoction of the tamarind, the latex being poured into the extract to ensure complete coagulation. The "tears" resembling resin on the outside of the lumps are characteristic of these species. The latices of *M. aucups* and *Landolphia Perrieri* are practically identical, but the former yields from 640 to 666 grms. of rubber per litre, and the latter only about 460 grms. per litre. A single plant of *M. aucups* will yield 1 litre of latex each season. *Mascarenhasia* latex cannot be coagulated by boiling or smoking and unlike that from the *Landolphia*, it is not properly coagulated by lemon juice, sakoa bark or decoction of *Vahea moniyum*. On the other hand a 3 per cent. solution of sulphuric acid will completely precipitate ten times its volume of latex.—J. K. B.

India-Rubber; Red Kasai —. E. de Wildeman and L. Gentil. India-Rubber J., 1904, 28, 622-623.

RED Kasai and Congo rubbers are obtained from the same species of vines, namely, the *Landolphia*, *Ouvriensis* Pal. Beauv., *L. Gentilii* De Wild and *L. Drogoumansiana* De Wild, and the difference in colour, which is the chief distinction, is probably due to the different climatic conditions in the two districts, and different modes of collecting and coagulating, and not to any inherent property of the latices. The *Landolphia Klaineri* also gives a reddish rubber when grown under the same conditions as the above mentioned species. The red colour of the rubber appears to be accentuated more and more as the district in which the vine is cultivated is farther from the zone known as the Great Equatorial Forest. In the south of the Congo territory, for instance, latitude 7° and 8° , the india-rubber collected is almost red. In the Upper Congo the latex from these varieties is very watery, whilst in the Kasai district it is thick. In the former district it is coagulated by means of Bosanga, and in the latter it coagulates spontaneously in contact with air.—J. K. B.

Leather, Leather Cloths, and Animal and Vegetable Fabrics; Manufacture and Waterproofing of —, P. C. D. Castle, Bebington, Cheshire. Eng. Pat. 2167, Jan. 28, 1904.

CLAIM is made for the addition of flour made from the locust bean to a low-nitrated cellulose solution, whereby the thickening and adhesive power of the latter is increased to such an extent as to allow of a sufficient quantity of the mixture being applied in one operation to render the material coated with it thoroughly waterproof. The coating liquid may be mixed with an oil such as castor oil.—M. C. L.

Gelatins and the like Solutions; Process and Apparatus for Evaporating —, C. B. Parkes, Whaley Bridge. Eng. Pat. 1144, Jan. 16, 1904.

A BEATED drum is caused to rotate in contact with the solution until the required thickness of semi-solid material has collected on the drum. The latter is then raised from the tank, or the supply of solution cut off, and the material on the drum further dried, and removed.

—W. P. S.

UNITED STATES PATENT.

Leather; Process of Treating [Waterproofing] Manufactured —, A. W. Case, Highland Park, Conn. U.S. Pat. 776,453, Nov. 29, 1904.

A SHEET of leather formed from a pulp of leather scrap is treated in a bath composed of melted wax or of a hot solution of a water-resisting substance, until the capillary cells of the material are completely filled.—A. S.

FRENCH PATENT.

Tannin Matters of Wood and Barks; Apparatus for the Extraction of —, in the Cold. A. Lautard. Addition dated July 30, 1904, to Fr. Pat. 338,300, Dec. 23, 1903 (this J., 1904, 615).

THE extractors described in the main patent (*loc. cit.*) may be replaced by vats of iron-cement (slag cement) closed hermetically. The vats described are in the form of long, horizontal cylinders.—A. S.

XV.—MANURES, Etc.

Ferrous Sulphate as a Fertiliser. E. Leclercq. Bull. Cercle Etudes Agron., Brussels, 1903. Eng. and Mining J., 1904, 78, 912.

THE author's experiments show that as a fertiliser for oats, 250 kilos. of copperas (ferrous sulphate) are equivalent to 150 kilos. of sodium nitrate, whilst the prices of the two compounds are as 1:5. The ferrous sulphate has the advantage also, that it acts as a weed-killer. It is stated that the fertilising value of the copperas lies in the iron, and not in the sulphuric acid.—A. S.

ENGLISH PATENTS.

Manure; Manufacture of Artificial —, from Sewage and other like Matter. W. Wardle, Burton-on-Trent. Eng. Pat. 25, Jan. 1, 1904.

THIS is an extension of Eng. Pat. 10,581 of 1903 (this J., 1904, 379). Refuse of a solid or semi-solid nature, such as "sewerage, blood, night soil, town refuse, ashpit collections, brewers' and distillers' or other like refuse" is mixed with a certain proportion (varied according to circumstances) of finely-ground gypsum, and of sodium chloride. The mixture is preferably heated or dried at a moderate temperature in an oven or kiln. (See also Eng. Pat. 6971 of 1901; this J., 1902, 183.)—E. S.

Nitrates or Similar Salts; Extraction or Preparation of —, J. C. W. Stanley. Eng. Pat. 4796, Feb. 20, 1904. VII., page 28.

XVI.—SUGAR, STARCH, GUM, Etc.

Sugar Canes; Raping —, according to Juice Density. Boname. Bull. Assoc. Chim. Sucr. Dist., 1904, 22, 405—407.

WITH the increasing centralisation of cane sugar manufacture it is of importance that a better basis for payment should be made than that of the mere weight of canes delivered. The density alone of the juice also is not sufficient, as juice of the same density gives very varying yields of sugar according to the variety of cane crushed: the yield of sugar therefore affords the only true basis in the interest of the manufacturer. It is also misleading in calculating the yield of sugar per acre to multiply the weight of canes by the average yield of the factory instead of by that of the particular variety of cane in question.—L. J. DE W.

Diffusion; Determined and Undetermined Losses in —, P. Herrmann. Bull. Assoc. Chim. Sucr. Dist., 1904, 22, 407—421.

THE author reviews the various causes which have been assigned for the losses in the diffusion battery, and finds that losses due to inversion of sugar by the acids present, and its destruction by micro-organisms or by enzymes are extremely small or nil. Apparent losses are often due to errors in analysis or bad sampling. The most reliable results are those of Claassen, as given below, which show only 0.10 to 0.15 per cent. of undetermined loss during diffusion:—

	1901-2.	1902-3.	1903-4.
Total losses	1.57	1.50	1.23
Determined	0.70	0.73	0.67
Undetermined	0.87	0.77	0.56
Losses in diffusion	0.64	0.70	0.63
Determined	0.52	0.55	0.53
Undetermined	0.12	0.15	0.10
Losses in working the juice	0.93	0.80	0.60
Determined	0.18	0.18	0.14
Undetermined	0.75	0.62	0.46

—L. J. DE W.

Undetermined Losses [Sugar Manufacture]. Hanns and Hruska. Z. Zuckerind. Böhmen, 1904, 28, 348.

THE authors found that in certain tests, diffusion juice to which milk of lime had been added, and which had then been carbonated, polarised less than the same juice clarified with basic lead acetate. This loss of polarisation was in two cases 0.18 per cent., which, for an extraction of 12.5 per cent. of juice, would correspond to a loss of 0.223

per cent. on the beetroots. They suppose that carbonation precipitates a dextrorotatory substance which, in the analysis of the scums, does not pass into solution again, and thus explains part of the undetermined losses in the sugar factory.—L. J. DE W.

Sugars; Action of Secondary Asymmetric Hydrazines on—, R. Offer. XXIII., page 47.

Sorbieritol [d-Iditol]; Synthesis and Chemical Nature of—, G. Bertrand. Comptes rendus, 1904, 139, 983—986.

The author has synthesised and isolated *d*-iditol from sorbose by reducing it by hydrogenation in an acid medium, and oxidising away the *d*-sorbitol simultaneously formed, by means of the sorbose bacterium. This hexahydric alcohol (*d*-iditol) is found to be identical with sorbieritol (extracted from the juice of sorb), which has the formula:—

It must be concluded that natural *d*-iditol originates from the hydrogenation of sorbose, which is derived from sorbitol by oxidation.—T. H. P.

Scammonose; So-called —, E. Votocek and R. Vondráček. Ber., 1904, 37, 4615—4616.

REQUIER has recently stated (J. Pharm. Chim., 1904, 20, 148-151 and 213-217) that he has obtained from scammonin (or scammonic acid), by boiling with dilute mineral acids, a saccharine syrup which deposits crystals of a pentose; this he describes provisionally as a methyl-tetrose. The authors cannot confirm these observations, as they find that the sugars obtained in the above way consist at most of traces of pentose and are mainly dextrose, rhodose, and another methylpentose, which is probably isorhodose. The name scammonose must therefore be discarded.—T. H. P.

ENGLISH PATENTS.

Sugar Cane, Beetroot, and the like; Treatment of —, R. Harvey, Glasgow. From L. Naudet, Paris, and H. C. Hinton, Madeira. Eng. Pat. 27,606, Dec. 17, 1903.

FRESH raw cane juice from the crushing mill is sulphured, mixed with milk of lime and heated to a suitable temperature. The juice is then pumped into a macerating vessel filled with fresh megasse, and previously drawn juice is added to fill the vessel completely. Forced filtration of the juices is effected by the aid of a pump, and when the filtration is complete, the megasse in the macerating vessel is exhausted by water, removed to a second cane-mill and pressed. The maceration vessels are worked in batteries of from 4 to 12 vessels, in such a way that the filtration and exhaustion are conducted as economically as possible.—J. F. B.

Cane Juice, Beet Juice, and other Liquids; Evaporators for —, R. Harvey, London. Eng. Pat. 28,617, Dec. 30, 1903.

THE combined heater and film-evaporator, for use with either single or multiple effects, has a calandria composed of a number of tubes fixed in two tube-plates, and surrounded by a vapour-jacket. The vapour-jacket has a number of holes in its inner wall, differing in size according to the distance from the steam inlet, and ensuring a

uniform supply of steam to all parts of the calandria. The bottom of the calandria is also surrounded by a steam-jacket. The tubes are maintained about a constant fall of juice, which being heated, boils up to the top, in such a way that the upper portions of the tubes are surrounded by evaporators. J. F. B.

Sugar Cane, Beet and other Juices or Liquids; Apparatus for Concentrating —, R. Harvey, London. Eng. Pat. 28,711, Dec. 31, 1903.

THE evaporator has a jacketed calandria fitted with three tube-plates, with a juice-space between the intermediate and the bottom tube-plates. Narrow tubes extend from the bottom tube-plate to the top one, through the juice-chamber. These narrow tubes are connected with the steam casing, and their interior is filled with steam. Wider tubes extend from the intermediate tube-plates to the top plate, and surround the narrow tubes, so as to form an annular passage which is supplied with juice from the juice chamber. Thus the film-evaporating tubes are heated with steam both inside and outside. — J. F. B.

Filters [Sugar]; Impts. in [Sand] —, J. Kostalek, Prague, Austria. Eng. Pat. 20,857, Sept. 28, 1904.

THE sand filter consists of a series of superposed cylindrical sections (4) fitted with cone-shelves (14), so constructed as to enable the sand to pass without hindrance to the base of the apparatus, the annuli (20) preventing the mixing of the filtered and unfiltered juice. Above and

below the shelves are perforated plates. The juice to be filtered entering at (5) is admitted by the automatic arrangement (7, 8) and passes through the sand (11) or overflows by the side inlets (13) to the space (3) between the shelves (14) and the perforated plates (16), through the sand downwards in parallel streams; the filtrate passing through the perforated plates (15) (Fig. 2) away by the outlets (18) where the outflow is controlled by regulating screws. To the base of the apparatus is connected the washing apparatus (21) with a horizontal hollow sliding injection tube (22) and junction piece (23), by means of which the sand, saturated with seum, is carried away by the flow of water under pressure through

the pipe (27) into the upper part of the filter, and thereby washed. The residue of juices flows off from the filter through the perforated funnel (25) and away by the opening (26).—L. J. B. W.

ENGLISH PATENT.

Sugar Malt: Process for giving Rapid Colour to Malt.—Eng. Pat. 339,168, Nov. 14, 1903.

See Eng. Pat. 2,779 of 1903; this J., 1904, 994.—J. F. B.

XVII. BREWING, WINES, SPIRITS, Etc.

Malt Desulphury: Application of Somblo's Process to Washed Malt.—G. Froeh. Z. Spiritusind., 1904, 27, 504.

THE author describes details of experiments made on the washing of green malt for distillery use with hot water, according to Somblo's process (see this J., 1904, 674). The malt was of very bad quality, the refuse of the malting floors, containing many crushed and damaged corns, sand, stones, &c., and in the ordinary way of working it was very mouldy. For the washing process, a disused yeast-tun was filled with hot water at 53°–55° C., and so much malt was introduced as sufficed to bring the temperature down to 50° C., after thorough mixing. Careful stirring was continued until the sound malt-corns had sunk to the bottom, whilst the debris, broken corns, rootlets, &c., were skimmed off the top. The stirring and skimming were then repeated for a second time and the malt was collected on a sieve. This malt was then placed in cold water in a second tun and cold water was introduced at the bottom by means of a hose, until the water which overflowed was free from impurities. Finally the washed malt was drained on a hurdle. In the case of very mouldy malt, lime may be mixed with the hot water with advantage. The washed malt was always used for the preparation of the yeast-mash, whereby a purer yeast was ensured. Mashies prepared with this malt fermented earlier and with greater intensity than those prepared from unwashed malt. The washing process involves a loss of about 2 per cent. of the available mashing space on account of the water absorbed by the malt.—J. F. B.

Beer Wort: Tables for Calculating the Original Percentage of Extract in —.—P. Lehmann and H. Stadlinger. Z. anal. Chem., 1904, 43, 679–687.

THE original gravity of the wort expressed, according to Continental custom, in terms of the percentage of extract [degrees Balling] is calculated by the formula $100(E + 2.0665A)/(100 + 1.0665A)$, in which E = the percentage of residual (unfermented) extract in the beer, and A = the percentage of alcohol by weight.

Since the calculation of this expression is a tedious operation, the authors have compiled tables, applicable to beers containing from 1.5 to 5 per cent. of alcohol in increments of 0.01 per cent., by reference to which the percentage of extract in the original wort can be calculated simply by multiplying the residual extract of the beer by a single factor which is indicated in one column of the table, and adding to the product a number indicated in another column.—J. F. B.

[Brewing] *Gauging by the Titrimetric Method.*—C. Bleisch. Z. ges. Brauw., 1904, 27, 877–879.

AFTER carefully testing the (sodium thiosulphate) titrimetric method of gauging the capacity of fermenting tuns and other brewing vessels, the author finds that the limits of experimental error in the method may be so wide as to lead to greater inaccuracy in the results than when direct measurement of the liquid is practised, or the pycnometric method is used for determining the gravity of the wort. It is therefore entirely unsuitable for the purposes of exact measurement, and must be restricted to approximate determinations, and as a check on results when the existence of any serious error in mechanical gauging is suspected.—C. S.

Wines: Reduction of the Amount of Sulphurous Acid in White.—P. Carles. J. Pharm. Chim., 1904, 20, 551–557.

THE amount of sulphurous acid (free and combined) added to white wines to develop their characteristics may reach as much as 0.4 gram. per litre. Aération has hitherto been the only means of effecting a reduction in the amount of this acid when once added, but the author points out that this method is uncertain in its results, and not very practicable on a large scale. Hydrogen peroxide is a much more satisfactory desulphurising agent. Thus, in experiments with different types of wines containing from 0.035 to 0.35 gram. of free sulphurous acid, and 0.09 to 0.607 gram. of free and combined sulphurous acid per litre, it was found that by the addition of 1 gram. of hydrogen peroxide (10 volume medicinal solution) to a litre of the wine, the amount of free acid was reduced on the average by 0.026 gram., and the amount of total sulphurous acid by 0.037 gram. The other effects of the treatment on the wine were a slight darkening in colour and occasionally a slight turbidity. All sulphurous odour was destroyed, whilst the aroma of the wine was not affected. The flavour was rendered softer, except when the amount of hydrogen peroxide added exceeded 3 grms. per litre, when a slight bitterness was sometimes perceptible.—C. A. M.

Barley: Direct Determination of Extract in —.—G. Merz. Woch. f. Brau., 1904, 21, 791–793.

THE most convenient and rapid method for determining the extract-value of brewing barley is by preparing a raw-grain wort by means of a diastatic malt-extract. The calculation of the results in terms of malt necessitates a knowledge of the relations between the extract of the barley and that of the malt obtained from it, according to the particular type of malt prepared and the methods of malting and kilning it is intended to employ. This ratio can, however, in most cases be ascertained or estimated by experience. The diastatic extract, which should be freshly prepared, is made from green malt, dried at 37.5° C., and extracted with water in the proportion of 1 : 2 for 6 hours. Twenty-five grms. of very finely ground barley meal are mashed in a beaker with 400 grms. of water, and about 0.5 c.c. of the diastase solution, 75 grms. of which have previously been weighed out for the experiment. The mash is slowly brought to the boiling point over an asbestos plate, and when it begins to boil, 6 drops of 33 per cent. caustic soda lye are added. The mash is boiled with constant stirring for 30 minutes, the evaporated water being replaced from time to time; it is then cooled to 50° C., and 8 drops of hydrochloric acid, sp. gr. 1.124, are added to neutralise the soda. At this stage, the rest of the 75 grms. of diastatic extract are added, and the temperature is raised in 20 minutes to 70° C., at which it is maintained until saccharification is complete. After cooling to 17.5° C., the total weight of the mash is brought up to 500 grms. by the addition of water, and the clear wort is filtered off.

The extract in the wort is then determined by means of the pycnometer, and the value is corrected by deducting the equivalent weight of the salt and of the extract present in the diastase solution (after coagulation of the albumin).—J. F. B.

ENGLISH PATENT.

Wort: Device for Agitating and Aerating —.—S. A. Ward, Sheffield. Eng. Pat. 2398, Feb. 1, 1904.

THE agitating device consists of a wide outer tube, terminating at the top in a bell-shaped mouth, which is covered by a deflecting plate at a slight distance above the mouth. Compressed air is conducted to the bottom of the wide tube by means of a central narrow tube. This air-tube terminates in a cup-shaped cap with a central cone, which distributes the air upwards in all parts of the annular space between the two tubes. The ascending current of air sucks the wort up through the annular space and causes it to be discharged through the bell-mouth at the top.—J. F. B.

UNITED STATES PATENT.

Mashing and Converting Process. C. H. Caspra, Newark, N.J., Assignor to J. P. Fitzgerald, Scranton, Pa. U.S. Pat. 776,999, Dec. 6, 1904.

A MIXTURE of ground malt and raw grain is mashed with water. The mash is then boiled under reduced pressure, the vapours being condensed and returned to the mash by forcing the condensed liquid upward into the mash, in order "to effect the filtration of the wort."—W. P. S.

FRENCH PATENT.

Spirits; Apparatus for Continuous Rectification of —. E. A. Barbet. First addition, dated July 9, 1904, to Fr. Pat. 343,488, April 16, 1904. (See this J., 1904, 1039.)

THE rectifying apparatus is caused to separate the various "tail" products at the same time as the "head" products, either by effecting the total exhaustion of the phlegms in the preliminary purification, the crude phlegms being treated at their full alcoholic strength, or else by not exhausting the phlegms but treating them at a low alcoholic strength. In either case, the extraction of the "head" products and the two principal classes of "tail" products causes a high degree of preliminary purification, facilitating the action of the rectifying column. Further, the special intermediate condenser of the rectifier is provided with a connection by which a portion of the condensed liquid is withdrawn, gauged, and returned direct to the purifying column.—J. F. B.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

(A).—FOODS.

Flour; Influence of Ozone on the Properties of —. K. Brahm. Z. Untersuch. Nahr. u. Genussm., 1904, 8, 669—673.

THE author's experiments show that the bread-making qualities of wheaten flour greatly deteriorate when ozone has been applied as a bleaching agent.—W. A. C.

Milk; Use of Methylene Blue to distinguish Cooked Milk from Raw —. Schardinger. XXIII., page 47.

Milk Sugar [in Milk] and Maltose; New Colour Reaction for —. A. Wöhlk. XXIII., page 47.

ENGLISH PATENTS.

Alimentary Products Constituting a Phosphated Vinegar. R. Combret, Paris. Eng. Pat. 20,885, Sept. 28, 1904. Under Internat. Conv., Sept. 28, 1903.

THE product claimed is prepared by dissolving in any suitable vinegar a variable quantity of either tricalcium phosphate (preferably in a freshly precipitated or gelatinous condition), dicalcium phosphate or monocalcium phosphate. In order not to diminish the acidity of the vinegar, the two first-mentioned phosphates may be dissolved in acetic, phosphoric or hydrochloric acid before being added to the vinegar. The phosphates may also be added during the acetic fermentation.—W. P. S.

Vegetable Food Stuffs; Production of Soluble Earthy-alkaline and Metallic Salts of the Organic Phosphorus Compound contained in —. S. Posternak, Paris. Eng. Pat. 22,030, Oct. 13, 1904.

TEN kilos. of the insoluble lime salt of the organic phosphorus compound obtained from vegetable foodstuffs, are dissolved in about 30 litres of 10 per cent. hydrochloric acid. The solution is then filtered and precipitated by the addition of about 35 litres of 95 per cent. alcohol. The precipitate is filtered off and pressed, the cakes being again mixed with alcohol, filtered off, and dried under reduced pressure at a temperature of 50°—60° C.

The product is a snow-white powder, which dissolves in water and consists of a dibasic salt. In a similar way, soluble salts of magnesium, calcium, or manganese can be prepared. (See also this J., 1904, 126.)—W. P. S.

Water and other Liquids; Sterilisation of —, and of Alimentary Substances to render the same Potable or Edible. V. B. Nesfield, London. Eng. Pat. Dec. 3, 1903. XVIII.B., page 39.

Gelatin or Gelatinous Foodstuffs; Impts. relating to —. J. Wetter, London. From the Thüringer Gelatine-Fabrik, E. Jetter and Kohn, Stuttgart, Germany. Eng. Pat. 22,952, Oct. 25, 1904.

A SOLUTION of casein is gelatinised by the addition of gelatin, and the jelly cut into sheets and dried, as in ordinary gelatin manufacture; the product being intended for use as a foodstuff.—M. C. L.

UNITED STATES PATENT.

Centrifugal [Milk] Separators; Liner for —. A. M. Amberg, Assignor to Nya Aktiebolaget Radiator, Stockholm, Sweden. U.S. Pat. 776,102, Nov. 29, 1904.

THE liner for a centrifugal separating-drum consists of a series of conical plates arranged one above the other. The liner is provided with distributing pipes, having division walls, dividing them into separate chambers. The distributing pipes have outlets, placed at different levels in the different chambers and caps at the upper ends, provided with outlet pipes.—W. H. C.

(B).—SANITATION; WATER PURIFICATION.

ENGLISH PATENTS.

Manure; Manufacture of Artificial —, from Sewage and other like Matter. W. Wardle. Eng. Pat. 25, Jan. 1, 1904. XV., page 35.

Water and other Liquids; Sterilisation of —, and of Alimentary Substances to render the same Potable or Edible. V. B. Nesfield, London. Eng. Pat. 26,495, Dec. 3, 1903.

THE water is treated with iodine or with a mixture from which iodine can be liberated. Such a mixture may consist of sodium iodide and iodate together with citric or tartaric acid. The sodium salts can be replaced by the corresponding potassium or calcium salts. Instead of using citric acid in the mixture, the iodine may be liberated in the water by aeration with carbon dioxide or by other means. The freed iodine is afterwards destroyed by the addition of sodium thiosulphate or sulphite. The iodine-liberating mixture and the thiosulphate may be added both together in the form of a pill or tablet, the outside of which consists of the iodide mixture and the core of thiosulphate, an isolating layer of gelatin or sugar being placed between the two. Solid alimentary substances are sterilised by immersing them in water in which iodine has been liberated as above.—W. P. S.

Water; Apparatus for Purifying and Softening —. C. Erith, London. Eng. Pat. 6946, Mar. 22, 1904.

THE apparatus consists of a heater, a reaction-tank, a settling tank and filter, and a storage tank. In the heater is suspended a series of inclined trays, over which the water and softening agent flow, steam being passed into the chamber to heat the mixture. The reaction-tank is placed beneath the heater, and is connected at its bottom with the settling tank. A layer of filtering material is provided across the latter at the top. After passing the filter the softened water flows over a partition into the storage tank. The supply of water and reagent to the heater is regulated by a float or ball-valve in the reagent tank or outside it. This float is connected by pivoted rods to valves in the water- and reagent-supply pipes. The softening reagent may be a solution of sodium carbonate. Means are provided for flushing the sludge from the tanks, and a vent in the heating chamber allows any liberated gases to escape.—W. P. S.

UNITED STATES PATENT.

Water: Process of Purifying ——. T. E. F. Jones, Assignor to A. A. Miller, Grand Junction, Colo., U.S. Pat. 776,508, Dec. 6, 1904.

THE water is treated with suitable proportions of a solution consisting of a saturated solution of sodium bicarbonate, 5 lb.; sodium carbonate, 5 lb.; and sodium borate, 1 lb. The treated water is agitated and aerated. After a trace of solution of ferric chloride is added, the whole again agitated and aerated, and then allowed to settle.—W. F. S.

FRENCH PATENT.

Chlorine or Oxygen Compounds of Chlorine: Process of Eliminating ——. from Water designed for Drinking, Industrial or Agricultural Uses. G. Demoussy. Fr. Pat. 339,163, Nov. 12, 1903.

THE process relates to the treatment of water which has been sterilised by means of chlorine or hypochlorites. Ferrous hydroxide or carbonate, prepared in any suitable manner, is added in quantity corresponding with the quantity of chlorine in the water, and the latter may also be charged with carbon dioxide, so as to form a solution of an unstable compound of iron. The peroxide of iron ultimately formed and precipitated purifies the water by carrying down organic matter.—B. N.

XIX.—PAPER, PASTEBOARD, Etc.

ENGLISH PATENTS.

Papers: Manufacture of Sensitised Copying ——. J. Hawke, New Barnet. Eng. Pat. 1857, Jan. 23, 1904.

IN order to prevent the destruction of the wire-work of paper-machines by the acid in the pulp, when ferric chloride has been used for sensitising it, an alkali bicarbonate is added. A solution of 42 lb. of potassium bicarbonate may be added to the pulp for making 1000 lb. of paper, which has been sensitised with 5 galls. of a 40 per cent. solution of ferric chloride.—T. F. B.

Wall-Papers: Manufacture of ——. such Papers being Applicable for other Decorative and Useful Purposes. A. Fielding, Salford. Eng. Pat. 2323, Jan. 30, 1904.

A MANUFACTURED (preferably unsized) paper is treated with a, e.g., 10 per cent. solution of viscose, and the viscose is fixed by ageing or steaming. The additional strength thus imparted to the paper enables it to be washed and dyed in the same manner as cloth, the viscose acting as a mordant for many dyestuffs. When the dyestuff to be used does not react with the viscose, or when a mineral pigment is used, the colour and viscose are applied as a mixture and the viscose fixed as usual. The paper thus produced has a silky appearance, and can be further decorated by printing or embossing. A paper suitable for lithographic and printing purposes is obtained by treating unsized paper with viscose, steaming, washing, bleaching, and calendering.—T. F. B.

Paper: Manufacture or Treatment of ——. for Printing. J. von Schmaedel Ritter, Munich, Germany. Eng. Pat. 8885, April 18, 1904. Under Internat. Conv., May 16, 1903.

SEE Fr. Pat. 342,206 of 1904; this J., 1904, 949.—T. F. B.

Paper: Grinding Wood for the Manufacture of ——. F. A. Werle, Breslau, Germany. Eng. Pat. 16,281, July 22, 1904. Under Internat. Conv., Nov. 28, 1903.

IS the "warm grinding" process for the manufacture of mechanical wood-pulp, the heat is generated by the friction of the stone on the wood, which is pressed very heavily against the stone. According to the present invention the useful effect of the heat in producing a fine, long-fibred material is obtained by using water at 60 to 80° C. for the grinding process, whereby the wearing away of the stones may be considerably decreased by lightening the pressure applied to the wood.—J. F. B.

Viscose: Apparatus [Heater] for Treating ——. F. W. Howorth, London. From Soc. Franç. de la Viscose, Paris. Eng. Pat. 2357, Jan. 30, 1904.

SEE Fr. Pat. 339,564 of 1904; this J., 1904, 725.—T. F. B.

FRENCH PATENTS.

Paper: Purifier for the Manufacture of ——. [Pulp Strainer]. P. Nelrich. Fr. Pat. 345,827, July 26, 1904.

SEE Eng. Pat. 16,403 of 1904; this J., 1904, 949.—T. F. B.

Vegetable Fibres [Paper Pulp]: Treatment of ——. C. Tennant-Lee. Fr. Pat. 345,632, Aug. 4, 1904.

VEGETABLE matters, particularly crushed sugar cane bagasse, are boiled in an alkaline, saccharine solution, such as a solution of calcium or magnesium succate. The time of boiling and the concentration of the solution are regulated so as to cause the minimum of damage to the delicate fibres.—J. F. B.

Paper: Manufacture of a New Type of Flexible and Strong ——. Soc. Cartiere di Maslianico. Fr. Pat. 345,836, Aug. 23, 1904.

PAPER is treated with sulphuric acid in the manner usually employed for the preparation of parchment paper, but the action is arrested before the acid has time to convert the interior of the sheet.—J. F. B.

Cellulose Acetates: Manufacture of ——. Fabr. de Prod. Chim. Flora, S.A. Fr. Pat. 345,764, Aug. 23, 1904.

CELLULOSE, 30 parts, is heated with a mixture of acetic anhydride, 70 parts, glacial acetic acid, 120 parts, and dimethyl sulphate, 3 parts, at the temperature of the boiling water-bath, until complete solution is effected. The product agrees in composition and solubility with cellulose tetracetate. A different product which is soluble in acetone and alcohol can be prepared by increasing the proportion of dimethyl sulphate to 15 parts.—J. F. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

Zinc Borate [or Oxyborate]: Preparation of ——. E. Holdermann. Archiv der Pharm., 1904, 242, 567—8.

FIVE hundred grms. of zinc sulphate (or a solution of about 115 grms. of metallic zinc in a mixture of 175 grms. of strong sulphuric acid and 2 litres of water) are dissolved in 5 to 10 litres of water and precipitated by the gradual addition, with constant agitation, of a solution of 443.6 grms. of borax and 309 grms. of a 15 per cent. solution of sodium hydroxide. The precipitate after washing and drying in the usual manner has the formula $Zn_3(B_4O_7)_2(OH)_2$.—J. O. B.

p-Phenetidine; Ethylsulphonic Derivatives of ——. and their Pharmacological Significance. W. Autenrieth and R. Bernheim. Archiv der Pharm., 1904, 242, 579—589.

AS soon as the fact was recognised that, in the organism, aniline becomes oxidised into the toxic *p*-aminophenol, steps were taken to substitute derivatives of *p*-aminophenol as antipyretics instead of the simple aniline derivatives, such as acetanilide; for although *p*-aminophenol is itself poisonous, its derivatives are for the most part relatively non-toxic.

The following ethylsulphonie derivatives of *p*-phenetidine are described:—

n-Ethylsulphone-p-phenetidine $(1)C_2H_5O.C_6H_4.NH.SO_2.C_2H_5(4)$ forms shining white leaflets, m.pt. 80—81° C.; it is obtained by the action of ethylsulpho-chloride on *p*-phenetidine. It is a monobasic acid and forms well crystallised salts.

n-Ethylsulphonephenacetine $C_2H_5O.C_6H_4.N(SO_2.C_2H_5)(COCH_3)$, forms leaflets m.pt. 78° C. insoluble in cold water; it is prepared by the action of acetic anhydride on ethylsulphone-*p*-phenetidine.

n-Ethylsulphonbenzoyl-*p*-phenetide, $C_2H_5O.C_6H_4.N(SO_2.C_2H_5)(CO.C_6H_5)$, in fine prisms, m.pt. 117° C.
n-Ethylsulphonmethyl-*p*-phenetide, $C_2H_5O.C_6H_4.N(SO_2.C_2H_5)(CH_3)$, in prisms, m.pt. 49° C.
n-Ethylsulphone-ethyl-*p*-phenetide, $C_2H_5O.C_6H_4.N(SO_2.C_2H_5)$ in prisms, m.pt. 57° C.
n-Ethylsulphone-*p*-phenetidine-carboxylic acid ethyl ester, $C_2H_5O.C_6H_4.N(SO_2.C_2H_5)(CO_2.C_2H_5)$, in crystalline leaflets, m.pt. 112° C.
p-Phenetidinecarboxylic acid ethyl ester, $C_2H_5O.C_6H_4.NH.CO_2.C_2H_5$, in colourless leaflets, m.pt. 93.5° C.
o-Nitro-*n*-ethylsulphone-*p*-phenetide, $(C_2H_5O)(NO_2).C_6H_3.NH.SO_2.C_2H_5$, in yellow needles, m.pt. 179° C.

—J. O. B.

Piperonal; Action of Magnesium-ethyl iodide on —.
New Synthesis of Isosafrol. E. Mameli, Atti R. Accad. dei Lincei Roma, 1904, 13, 315—323. Chem. Centr., 1904, 2, 1567-1568.

ETHEREAL solutions of magnesium-ethyl iodide and piperonal were mixed, and the reaction product was treated with water. In this way the hitherto unknown

ethylpiperonyl alcohol (3-4-methylene-3, 4-dioxycyclopropane-1-ol), $(CH_2O_2.C_6H_4.CH_2OH).C_6H_5$, was produced. It is an oil with a faint odour, sp. gr. 1.15, n_D 1.5189, b. pt. 172—175° C.; it is soluble in ether, petroleum spirit, chloroform, alcohol, acetic acid, and pyridine, but insoluble in water. When heated it decomposes, a molecule of water being split off, and yields (3, 4-methylene-3, 4-dioxycyclopropyl-1-propene), $(CH_2O_2.C_6H_4.CH:CH.CH_3)$, formed. On oxidation with chromic acid mixture, ethyl-piperonyl alcohol yields propopiperone or piperonyl-ethyl ketone (3, 4-methylene-3, 4-dioxycyclopropyl-1-propane-1-one), $CH_2O_2(C_6H_4.CO.C_2H_5)$. A. S.

Essential Oils of Eucalyptus [Constituents of the Oils of Various Species]. H. G. Baker and R. T. Smith. Schimmel's Report, Oct., 1904, 31—37.

The following table indicates the botanical and geographical sources, the percentage yield, and the main chemical constituents of the essential oils of eucalyptus examined by the authors:—

Botanical Name.	Vernacular Name.	Geographical Origin.	Average percentage yield of oil.	Principal Chemical Constituents.
<i>E. tessellaris</i> F. v. M.	Moreton Bay, Ash	Narrabri, N. S. W.	0.151	Pinene, sesquiterpene.
<i>E. trachyphloia</i> F. v. M.	Bloodwood	Murrumbidgee, N. S. W.	0.199	Pinene, sesquiterpene.
<i>E. cymia</i> R. T. B.	Thin Bloodwood	Springwood, N. S. W.	0.462	Pinene.
<i>E. botryoides</i> Sm.	Bastard Mahogany	Milton, N. S. W.	0.086	d-Pinene.
<i>E. robusta</i> Sm.	Swamp Mahogany	La Perouse, N. S. W.	0.161	Pinene.
<i>E. saligna</i> Sm.	Blue Gum	Gosford, N. S. W.	0.241	Pinene.
<i>E. nana-anglica</i> D. & M.	Black Peppermint	Walcha, N. S. W.	0.51	Terpenes.
<i>E. umbra</i> R. T. B.	A Stringybark	Lismore, N. S. W.	0.1615	Pinene, also an acetic acid ester
<i>E. dextropinea</i> R. T. B.	Stringybark	Barber's Creek, N. S. W.	0.798	d-Pinene.
<i>E. Wilkinsoniana</i> R. T. B.	Small Leaved Stringybark	Barber's Creek, N. S. W.	1.01	1-Pinene.
<i>E. laevopinea</i> R. T. B.	Silver Top Stringybark	Rylstone, N. S. W.	0.66	1-Pinene.
<i>E. Buerkeri</i> F. v. M.	Brown Gum	Monga, N. S. W.	0.328	
<i>E. propinqua</i> D. & M.	Grey Gum	Woodburn, N. S. W.	0.235	Terpenes, cineol [eucalyptol], chiefly the former.
<i>E. affinis</i> D. & M.	Black Box	Grenfell, N. S. W.	0.259	
<i>E. paludosa</i> R. T. B.	Swamp Gum	Barber's Creek, N. S. W.	0.197

Santalal and Sandalwood Oils. Seidler, Apoth. Zeit., 1901, 19, 795. Pharm. J., 1904, 73, 813.

A good sample of East Indian sandalwood oil should be of a pale yellow colour, and the greater portion of it should distil between 297° and 305° C. It should have the specific gravity, 0.975–0.985; optical rotation, –17° to –19°; solubility in 70 per cent. (by volume) alcohol, 1:5; acid value, not above 2.75; saponification value, not above 7.5; acetyl-saponification value, not below 197. Santalol, the active constituent of sandalwood oil should have a sp. gr. of at least 0.980; optical rotation, –18° to –19°, and should form a clear solution with 4 parts of 70 per cent. (by volume) alcohol. It should distil mainly between 302° and 306° C.—A. S.

Lichens: Characteristic Constituents of —. O. Hesse, J. prakt. Chem., 1904, 79, 449, 502. (See also this Journal 1901, 161.)

The acids were isolated by extracting with ether and shaking out the ethereal extract with potassium bicarbonate solution.

Cladonia squamosa (Hoffm.) *frondosa* (Nyl.). The only characteristic principle isolated from this lichen was a squamatic acid $C_{15}H_{26}O_6$.

Cladonia (Cladonia) destriata (Nyl.) contained l-ustinic acid, m.p. 196–197° C.; $[a]_D^{25}$ –495.9 in chloroform solution at 15° C. and $c = 2$; also squamatic acid, cladestin and a colouring matter. Cladestin occurs as a white crystalline powder, m.p. 252° C. It is neutral; insoluble in alkalis and water, dissolved in strong sulphuric acid with a deep yellow colour, which passes to ponceau red on warming.

Cladonia furcata (Huds.) Fr. β (*racemosa* b) *recurva* Hoffm. This lichen yielded only a trace of an acid to potassium bicarbonate.

Cetraria islandica (L.). The author was unable to

isolate the acid described by R. Boehm (Archiv Pharm.) 241, 3, 4), having the composition $C_{19}H_{32}O_4$, but obtained proto-a-lichesteric acid $C_{13}H_{26}O_5$; fumaric acid, both free and combined; fumariprotocetraric acid, $C_{26}H_{46}O_{13} + 2H_2O$, in small white needles, which turn brown at 240° C. and black without melting, at 260° C. Protocetraric acid, $C_{54}H_{102}O_{27}$, was obtained by saturating fumariprotocetraric acid with half a molecular equivalent of alkali. It crystallises from hot solutions in spheroidal aggregations. It is slightly soluble in water when freshly precipitated. From another closely allied lichen, *Cladonia rangiferina*, var. *rutgaris*, fumariprotocetraric acid was obtained.

Parmelia saxatilis var. *sulcata* and var. *panniformis* both gave an acid, parmatic acid, at first considered to be fumariprotocetraric acid, but which yielded no sublimate of fumaric acid on heating.

Parmelia borreri (Turn.) was found to contain lecanoric acid as stated by Zopf (Annalen, 313, 331), and also a small amount of lecanorin, which was not found by that author.

Parmelia tinctorum (Despreaux, Nyl.) on the bark of East Indian *Cinchona officinalis*, contained lecanoric acid and atranorin.

Parmelia perlata L. also on *Cinchona* bark, distinguished from *P. tinctoria* by not giving a red colour-reaction when touched with chlorinated lime solution, gave atranorin and perlatic acid, $C_{27}H_{42}O_9 \cdot OCH_3 + 2H_2O$, crystallising in white needles. This becomes partially dehydrated at 80° C., melts at 90–95°, but does not become anhydrous below 110° C. The water-free acid melts at 100–105° C. when slowly heated, and at 125–130° C. when the temperature is quickly raised. Its alcoholic solution reddens blue litmus.

Parmelia caperata, L., contained d-ustinic, capraric and caperic acids, the last two predominating. No caperin was found.

Sticta pulmonaria L. (Schaerer), was found to contain new acid named stictic acid, $C_{17}H_{11}O_8 \cdot OCH_3$, crystallizing in faintly yellow needles, containing water of crystallization, which is driven off at 100° C.; it becomes coloured at 240°, and melts at 264° C. It is monobasic, has the same percentage composition as, and is closely related to, protocetraric acid. Its alcoholic solution, when heated with sulphuric acid gives a brown, not blue, colour.

Aspicilia gibbosa (Kbr.) contained two acids, one not obtained in sufficient amount for identification; the other picillic acid, forming colourless leaflets melting at 9° C. The chief constituent of the lichen is an indifferent crystalline body, aspicillin, isolated, after removing the acid, as colourless shining leaflets, melting at 150° C. and stilling at a higher temperature without decomposition. *Urcularia scruposa* var. *vulgaris* (Ach.) The author is isolated atranorin and lecanoric acid $C_{16}H_{11}O_7 + 2O$, from this lichen; Zopf (Annalen, 324, 74) has stated that it contains patellarie acid.

Chiodecton sanguineum (Sw.) = *Ch. rubrocinctum* (Ehrh.) on Bolivian cinchona bark, slowly yields a red colouring matter to ether, chiodectonic acid $C_{14}H_{18}O_5$. After removing this acid, another red neutral, crystalline body, chiodectin, remains in the ethereal solution; when purified, it melts at 120° C.

Pertusaria dealbata (Nyl.) yielded no crystalline constituents to ether. Orcin, previously recorded as present, was not found.—J. O. B.

Vanillin; Occurrence of —. E. O. von Lippmann. Ber., 1904, 37, 4521—4522.

A VERY strong odour of vanillin has often been observed in the neighbourhood of wooden structures in which salt is dried, and, on scraping the surface of the wood, the author finds that the scrapings contain this substance. Krafé (this J., 1904, 1158) has recently shown that wood contains a small quantity of vanillin.—T. H. P.

ENGLISH PATENTS.

Iron-Peptide or Iron-Manganese-Peptide; Production of a Stable, Non-alcoholic Solution of —. S. S. Bromhead, London. From Chem. Fab. Helfenberg, Ltd., formerly E. Dieterich, Dresden, Germany. Eng. Pat. 20,273, Sept. 20, 1904.

SOLUTIONS of iron-peptide or iron-manganese-peptide containing 0.6 per cent. of iron, and 0.1 per cent. of manganese are prepared, free from alcohol, by dissolving the commercial compounds in water slightly acidified with hydrochloric acid. The solution is cooled to 0° C., and impregnated with carbon dioxide at a pressure of 3 atmospheres. It is then stored in closed, air-tight bottles for 2 or 3 months at a low temperature, whereby an unstable combination of the carbonic acid is formed, and the medicinal compound is protected from decomposition and oxidation.—J. F. B.

Aldehydes; Manufacture of Certain —, and Intermediate Products [Perfumes]. G. Darzens, Paris. Eng. Pat. 21,047, Sept. 30, 1904. Under Internat. Conv., Nov. 28, 1903.

See Fr. Pat. 337, 175 of 1903; this J., 1904, 455.—T. F. B.

Phenylmethylamidochloropyrazole; Manufacture of —. Farbwerke, vorm. Meister, Lucius und Brüning, Höchst on-Maine, Germany. Eng. Pat. 22,064, Oct. 13, 1904. Under Internat. Conv., Nov. 11, 1903.

1-PHENYL-3-METHYL-4-AMINO-5-CHLOROPYRAZOLE is obtained by treating 1-phenyl-3-methyl-4-arylazo-5-chloropyrazole with an acid reducing agent. On reducing phenetol-azo-chloropyrazole in a similar manner, aminochloro-pyrazole is produced. Methylation of the phenylmethylaminochloropyrazole produces phenylmethylmethylaminopyrazolone.—T. F. B.

UNITED STATES PATENT.

Ammonium Formate; [Electrolytic] Process of Manufacturing —. H. Pauling. U.S. Pat. 776,543. Dec. 6, 1904. XI.A., page 32.

FRENCH PATENT.

Amino-Alcohols and their Derivatives, Process for Preparing —. Pauline Tréres and E. F. Tréres. Fr. Pat. 339,131, Oct. 29, 1903.

AMINO-ALCOHOLS of the general formula

are prepared by the action of organo-magnesium halides on dialkyl-, diaryl-, or alkyl-aryl amino-acetones, or by the action of a substituted fatty amine on the halohydrin of the constitution $RR''C(OH)CH_2X$, where X represents a halogen atom. The acylid derivatives of the amino-alcohols are also claimed. The following amino-alcohols are described:—Ethylidimethylaminopropanol, propyldimethylaminopropanol, isobutyldimethylaminopropanol, isoamylidimethylaminopropanol, ethylidimethylaminobutanol, phenylmethylaminopropanol, phenylidimethylaminopropanol, phenyldiethylaminopropanol, phenyldimethylaminobutanol, benzylidimethylaminopropanol, and α -methylidimethylaminopropanol. Many of these compounds are applicable to perfumery. (See also Fr. Pat. 338,889 of 1903; this J., 1904, 910.)—T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Hydrogen Peroxide; Radio-active-like Phenomena of —. L. Graetz. Physik. Zeits., 1904, 5, 688—690. Chem. Centr., 1904, 2, 1561.

HYDROGEN peroxide acts on a photographic plate in the same way as light: a radiation proceeds from the peroxide, capable of penetrating paper, ebonite, and thin metal foil. It is shown that the action is not due to hydrogen peroxide vapour, ozone, oxygen, or other substances. Contrary to the statement of Schenck and Richarz, the author finds that ozone has no action on a photographic plate. Objects can be photographed by placing them on the reverse side of a plate subjected to the influence of hydrogen peroxide, the images produced being light or dark according to the experimental conditions. The phenomena depend, in the first instance, upon differences of temperature in the plate. All the parts that are warmer than those adjoining, appear light on a dark ground, and *vice versa*. A difference of even $\frac{1}{50}^{\circ}$ C. becomes perceptible in this manner. The lightness or darkness of the image is not uniform throughout, "edge effects" being produced. Those places from which the heat proceeds appear black, whilst those to which it travels, appear white. The essential point is thus not the temperature, but the fall of temperature. The author concludes that there is a non-thermal difference between the poles of a heat-current, just as with an electric current. In the discussion the author remarked that there may be present in commercial hydrogen peroxide a resinous substance to which the activity may be due.—A. S.

Sodium Hydrosulphite and some Organic Hydrosulphites; Developing Properties of Pure —. A. and L. Lumière and A. Seyewetz. Brit. J. Phot., 1904, 51, 1086—1087.

HYDROSULPHUROUS acid alone has been found to possess some developing properties, but the images obtained were weak and fogged. Sodium hydrosulphite, prepared by the action of sodium bisulphite on zinc, gave still poorer results. Pure anhydrous sodium hydrosulphite (see Eng. Pat. 2204 of 1903; this J., 1903, 1347), however, acts as a vigorous developer in aqueous solutions, but fogged negatives result by prolonging the development. It is found that this tendency can be overcome by the addition of potassium bromide and sodium bisulphite, the following composition having been proved satisfactory:—Sodium hydrosulphite, 20 grms.; "commercial" sodium bisulphite, 100 c.c.; 10 per cent. solution of potassium bromide, 70 c.c.; water, 1000 c.c.; with this developer a normally exposed negative will be fully developed in about 3 minutes. Excess of sodium bisulphite does not appreciably prolong development. The hydrosulphites

of dinitronaphthalene, dinitroresorcinol, trinitronaphthalol, nitrovinylol, and other organic nitro compounds, obtained by mixing concentrated solutions of sodium cyanosulphate and the monochloride of the base, were found to possess the following properties when used in an explosive mixture: (1) Addition of sulphuric acid, sodium chloride, and bromide increased the stability, but gave rise to the formation of excessive heat. The hydrochlorates of aromatic monamines appear to possess the following properties. —T. F. B.

ENGLISH PATENT.

Explosives. Photographs: Manufacture of —. — J. P. Welch, London. From Act-Ges. f. Angewandte Chemie. Eng. Pat. 3794, Feb. 15, 1904.

SEE FI. Pat. 340,459 of 1904; this J., 1904, 836. —T. F. B.

XXII.—EXPLOSIVES, MATCHES, Etc.

Nitro-derivatives of the Anthraquinone Series. — R. Scholl, Ber., 1904, 37, 4427–4448.

AMINOANTHRAQUINONES and their nuclear substitution products are converted by treatment with nitric acid of sp. gr. 1.50 to 1.52 into nitrated nitramines. The nuclear nitro groups replace some or all of the hydrogen atoms in *ortho*- or *para*-position to the original amino groups. These nitrated nitramines are stable at ordinary, but explosive at higher temperatures. The explosibility increases with the number of nitro groups. 2,4,6,8-Tetranitro-1,5-dinitraminoanthraquinone explodes on slight heating, on percussion, and on contact with gaseous ammonia, with formation of red smoke. It is obtained by adding 1,5-diaminoanthraquinone gradually with stirring and cooling in a freezing mixture to ten times its weight of colourless nitric acid of sp. gr. 1.52 and pouring into ice-water. It is soluble in acetic acid, very soluble in acetone, and can be precipitated from the latter solution by methyl alcohol. It is converted into a red, crystalline, explosive product, with evolution of gas, on boiling with glacial acetic acid. This reaction is helped by the presence of a few drops of concentrated sulphuric acid. —E. F.

ENGLISH PATENTS.

Explosives. — H. H. Lake, London. From Cyanid-Ges. m. b. H., Berlin. Eng. Pat. 27,515, Dec. 15, 1903.

IN order to reduce the temperature of the gases produced by the detonation of explosives, without diminishing their disruptive power, mono-, di- or tri-cyanamide, or a salt of one of these (e.g., the calcium salt or the oxalate), or a mixture of these substances is added to the explosive. Any explosive may be used for this process, the following being claimed:—Those containing nitrocellulose; nitrocellulose and nitroglycerin; oxidising substances (nitrates, chlorates, &c.); oxidising substances mixed with oxidisable substances (e.g., aluminium, tatts, &c.). The cyanamide compound is preferably added in quantity sufficient to convert the oxygen evolved by the explosive into carbon monoxide; if nitrous acid be a normal constituent of the resulting gases, sufficient cyanamide is added to reduce it completely to nitrogen. The following compositions are given:—(1) Cyanamide, 4 parts; nitroglycerin, 93 parts; nitrocellulose, 3 parts. (2) Cyanamide, 5 parts; nitroglycerin, 58 parts; gum-cotton, 37 parts. (3) Cyanamide, 5 to 15 parts; ammonium nitrate, 95 to 85 parts. —T. F. B.

Safety Explosives [Ammonium Nitrate]. — The Miners Safety Explosive Co., Ltd., London, and W. Levett, Stanford-le-Hope, Essex. Eng. Pat. 4742, Feb. 26, 1904.

THE explosive is made from 2 components. [A] Ammonium nitrate (95½ parts) is ground for ½ hour at 180° F. Trinitronaphthalene (4½ parts) is then added, and the grinding continued for ½ hour. [B] Sodium nitrate (80 parts) and dinitronaphthalene (20 parts) are treated in the same manner. When cold, the two components are broken up, sifted, and mixed together in the proportions of [A] 33 parts, [B] 67 parts, or [A] 50 parts [B] 50 parts, or [A] 67 parts [B] 33 parts. —G. W. McD.

Gunpowder Shots: Machine for Use in the Manufacture of —. — J. Luciani, Paris. Eng. Pat. 21,398, Oct. 5, 1904.

SEE FI. Pat. 339,022 of 1903; this J., 1904, 1113. —T. F. B.

UNITED STATES PATENT.

Explosive and Process of Making Same. — A. Müller-Jacobs, New York. Assignor to C. Müller-Jacobs, Brooklyn and E. Weingartner, New York. U.S. Pat. 777,125, Dec. 13, 1904.

THE explosive is made by printing upon or impregnating nitrocellulose or other explosive cellulose compound with an aqueous solution of ammonium picrate and potassium chlorate, thickened by a suitable adhesive, such as gum tragacanth. —T. F. B.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS, ETC.

Oxygen in Coal-Gas: Automatic Test for —. — F. Kropf, J. Gasbeleucht., 1904, 47, 1103–1104.

LEYBOLD has shown that, in the practice of admitting small proportion of air to the crude coal-gas, for the purpose of effecting a continuous regeneration of the oxide in the purifiers, the presence of even a small excess of oxygen tends to render the oxide hard and removable only with difficulty from the purifiers; the water-absorbing power and proportion of active substance are lessened, and the oxygen brings about a rapid destruction of the gas-holder plates. A continuous, automatic test, capable of indicating the presence of more than 0.1 per cent. of volume of oxygen (equal to 0.5 per cent. of air in excess) has been devised by the author; it is based on the fact that oxide, which has been saturated with sulphuretted hydrogen, emits heat when air is led over it according to the equation: $\text{Fe}_2\text{S}_2 + \text{S} + 3\text{O} + 3\text{H}_2 \rightarrow \text{Fe}_2\text{O}_3(3\text{H}_2\text{O}) + 3\text{S} + 145 \text{ calories}$. The heat generated is perceptible if the proportion of oxygen does not fall below 0.1 per cent. The apparatus used is shown in the accompanying figure.

The gas, mixed with excess of sulphuretted hydrogen, passes in succession through two flasks, the first of which contains some water and one bulb of a differential thermometer, whilst the second contains at the bottom small pieces of coke, upon which there is a layer of oxide, about 5 cm. thick, surrounding the second bulb of the thermometer. The water in the first flask saturates the gas with moisture and prevents the drying of the oxide, whilst the sulphuretted hydrogen prevents the exhaustion of the purifying material, by re-forming Fe_2S_2 immediately should oxidation occur. The flasks are of 300–400 c.c. capacity. The bulbs of the thermometer, which hold about 3 c.c., are filled about one-third with ether. When the mercury column reaches a predetermined position an electrical contact is established between the wires of the bell circuit, as shown in the figure. The presence of oxygen is therefore indicated by the rise of temperature in the oxide. The oxide must be renewed at least once a fortnight, as its sensitiveness gradually diminishes

different varieties of oxide exhibit very different increments of temperature for a given percentage of oxygen in the gas (thus, 0.2 per cent. of oxygen gave readings varying from 1.7° to 3.4° C. with different preparations); but with the same kind of oxide, approximately uniform results are obtained.—H. B.

Photometer for Testing the Illuminating Values of Ordinary and High-Power Auer Burners. C. Carpenter and J. W. Helps. Paper read before the Internat. Commission on Photometry, Zurich; June, 1903.

In order to overcome the difficulty experienced in testing incandescent burners against the standard 10-candle pentane lamp or the carcel lamp, the burner to be tested is not compared directly with the standard lamp, but with a "secondary standard" which has previously been set to the same illuminating power as the standard, and which is obtained by surrounding an incandescent burner with an opaque screen in which is cut a vertical slot, provided with a sliding shutter for regulating the amount of light emitted. Two horizontal graduated bars are used, each carrying a disc-box; they may be arranged at any convenient angle to each other, or in the same straight line, but in any case the secondary standard burner (a Kern burner consuming $3\frac{1}{2}$ cu.ft. of gas per hour) is mounted rotatably at the junction of the two bars, at the other extremities of which are situated the burner to be tested and the standard lamp respectively. On making a test, after the lamp and burners have been alight for a sufficiently long period, the slot of the secondary standard is regulated by means of the sliding shutter until the light emitted is exactly the same as that given by the standard (1 carcel or 10 candles, as the case may be). The secondary standard is then rotated until the index pointer which it carries, coincides with the secondary bar, whereupon direct comparisons with the burner under examination are made. It is stated that when once set, the secondary standard remains constant for several hours; but it can easily be verified at any time by comparison with the standard lamp. As the lights are of equal intensity, though differing in colour, this can be done with great accuracy.—H. B.

ENGLISH PATENT.

Furnace Gases; Method of and Apparatus for Ascertaining the Quantity of Carbonic Acid in —. A. Schlatter and L. Deutsch, Budapest, Hungary. Eng. Pat. 28,262, Dec. 23, 1903.

SEE FR. Pat. 337,992 of 1903; this J., 1904, 561.—T.F.B.

INORGANIC—QUALITATIVE.

Silicic Acid; Detection of —. J. Petersen. Z. anal. Chem., 1904, 43, 619—623.

A METHOD is described for utilising the silicon fluoride test for substances containing as little as $\frac{1}{2}$ per cent. of silicic acid. The reaction takes place in a small platinum crucible of 20 mm. diameter (Fig. 1), into which 0.5 gm. of the substance, 0.25 gm. of cryolite or fluorspar and a few mgrms. of magnesite are introduced and a little sulphuric acid added, preferably from a dropping bottle. The crucible is provided with a handle of platinum wire, and is lowered into the test-tube by a hook also of platinum wire (Fig. 2). A drop of water is then suspended over the crucible on a glass rod, which is widened at the lower end, as shown, and coated with black asphalt varnish. The glass rod and test-tube are protected from the hydrofluoric acid vapours by treating with collodion containing 2 per cent. (by volume) of castor oil. The tube is then warmed in the water-bath for 5 minutes at 50°—60°C.; a higher temperature is inadmissible on account of the collodion. If much silica is present, bubbles form

Fig. 1 Fig. 2

which must be broken by tapping the tube. The separated silica shows up clearly on the black sand.—F. Sdx.

INORGANIC—QUANTITATIVE.

Potassium Chlorate; Action of Hydrochloric Acid on [Determination of] —. A. Kolb and E. Daxenroth. Z. angew. Chem., 1904, 17, 1883—1887.

THE authors have experimented on a method for the determination of potassium chlorate with hydrochloric acid and potassium iodide at the ordinary temperature, thus avoiding distillation. They find that the presence of oxygen especially that dissolved in the reagents causes too much iodine to be liberated, but good results are obtained when all air is expelled by previous boiling, and the operations are conducted in an atmosphere of carbon dioxide. By using a large excess of hydrochloric acid, the reaction is complete in a few minutes, but the addition of much water retards it. The disturbing oxidation of the hydrogen iodide by air does not occur on dilution, it is concluded, therefore, that only undissociated molecules are affected. The iodine liberated was titrated with thiosulphate in the usual manner.—F. Sdx.

Hydrogen Peroxide; Colorimetric Valuation of —. P. Planès. J. Pharm. Chim., 1904, 20, 538—541.

POTASSIUM iodide reacts with hydrogen peroxide forming potassium hydroxide and iodine, which in turn react upon each other with the formation of iodate and other iodine derivatives. This secondary reaction can be entirely prevented by the addition of sulphuric acid, so that the original reaction can be represented by the equation:—

$2KI + H_2O_2 + H_2SO_4 = K_2SO_4 + 2H_2O + I_2$,
according to which 1 gm. of iodine corresponds to 43.75 c.c. of oxygen, or 1 c.c. of oxygen to 0.022857 gm. of iodine. In the colorimetric method, based on this reaction, 20 c.c. of the hydrogen peroxide solution previously diluted to a tenth of its strength are treated with 12 c.c. of a 10 per cent. solution of potassium iodide, and 4 c.c. of dilute sulphuric acid (8 per cent.), and the resulting coloration matched by means of a standard solution of iodine.

—C. A. M.

Iodine in Soluble Iodides, and in Mixtures of these with Bromides and Chlorides; Determination of —. H. Ditz and B. M. Margosches. Chem.-Zeit., 1904, 28, 1191—1194.

IN this J., 1900, 933, a new process for determining potassium iodide, by T. S. Barrie, has been described. A solution of potassium iodide in the presence of chloride or bromide, may be treated with one of potassium bichromate and dilute sulphuric acid. Iodine alone is liberated, and is extracted by shaking with toluene (as an immiscible solvent) the iodine being subsequently titrated with thiosulphate. The present authors in their method, propose, however, to use as oxidising agent potassium iodate, and either dilute hydrochloric or sulphuric acid, $KIO_3 + 5KI + 6HCl = 6KCl + 3H_2O + 3I_2$, otherwise proceeding as in Barrie's process, *loc. cit.*—A. S.

Silica Determinations [in Iron Ores and Limestones]. H. E. Ashley. The Chem. Eng., Nov., 1904. Chem. News, 1904, 90, 274.

IN the analysis of iron ores, a simple extraction with hydrochloric acid may leave (1) a part, or (2) the whole of the silica as an insoluble residue. In the first case the solution (extract) must be evaporated to dryness, the residue treated with hydrochloric acid, and the silica filtered off, these operations being repeated if necessary. The silica thus obtained is added to the original insoluble residue, and the whole of the insoluble matter is then ignited and weighed, and the amount of silica present, determined by the loss of weight caused by treatment with hydrofluoric and sulphuric acids. In the second case the insoluble residue is directly ignited, weighed, and treated with hydrofluoric and sulphuric acids. The amount of silica in high-grade limestones may be determined in a similar manner. After dissolving the limestone in hydrochloric acid, evaporating the

solution to dryness, treating the residue with hydrochloric acid, and filtering, and then repeating these operations. About one-half of the insoluble residue consists of silica. S. V. Poppel has found that with lower grade ores the loss of weight in treating the insoluble residue with hydrofluoric and sulphuric acids is greater than the amount of silica present.—A. S.

Manganese in Cyanide Solutions: Colorimetric Determination (J. D. Jones, *Trans. J. E. Chennell, Eng. and Mining J.*, 1904, 78, 827).

Impurities of manganese in cyanide solutions may have a considerable influence on the extraction and precipitation of gold, and it also interferes in the determination of cyanide by titration with silver nitrate. The manganese may be removed by treating the cyanide solution with sodium sulphide, and removing excess of the latter by agitation with lead carbonate. For the detection and determination of the manganese, 100 c.c. of the cyanide solution are treated with 10 c.c. of concentrated nitric acid, the liquid is heated to boiling, 0.5 gram of lead peroxide added gradually, and after continuing the boiling for a few minutes, the mixture is allowed to settle. If manganese be present, a pink coloration appears, due to the formation of permanganic acid. The solution is made up to 100 c.c. with distilled water which has been previously boiled and filtered, the first 10 c.c. of filtrate being rejected. The colour of the next 50 c.c. of liquid is then matched against a solution prepared by adding to distilled water a standard solution containing 0.1435 gram of potassium permanganate and 10 c.c. of nitric acid per litre.—A. S.

Copper [in Ores, Mattes, &c.]: Iodometric Determination of — (A. M. Fairlie, *Eng. and Mining J.*, 1904, 78, 787—788).

In determinations by the iodometric method, the precipitation of copper by aluminium occupies considerable time, and has several other disadvantages. The author has made determinations much more quickly and simply by using ammonium or potassium thiocyanate to precipitate the copper. The cuprous thiocyanate is dissolved in strong nitric acid, the solution boiled until red fumes are no longer evolved, then neutralised with ammonia, acidified with acetic acid, potassium iodide added and the copper determined in the usual manner.—A. S.

Copper [in Copper Pyrites]: Determination of —, in Presence of Iron and Arsenic, by the Iodide Method. (L. Moser, *Z. anal. Chem.*, 1904, 43, 597—616).

The author has adapted the iodide method for determining copper in the presence of iron and arsenic, by adding excess of sodium pyrophosphate ($\text{Na}_2\text{P}_2\text{O}_7$) in which all three dissolve forming complex ions. Of these ions, only that containing copper is decomposed by acetic acid (sulphuric acid breaks up all), and on adding potassium iodide therefore only cuprous iodide is precipitated, but it is important to allow time for this, about 15 minutes sufficing. Working conditions are made clear by a description of an actual analysis of copper pyrites containing 27.25 per cent. of copper and 31.84 per cent. of iron. About 2 grams were digested, with shaking, for 1 hour in the cold with a little fuming nitric acid, and then more nitric acid was added, and the oxidation of the sulphur completed on the water-bath. The nitric acid was displaced by sulphuric acid, and excess of this driven off almost completely on a sand-bath. The residue was taken up with water, and sodium acetate added, which gave a brown solution. The silica and lead sulphate were filtered off and washed with hot water, and the filtrate made up to 100 c.c.; 20 c.c. of this were precipitated with solid sodium pyrophosphate, and the precipitate dissolved in a little strong solution of the same reagent, when a blue solution was obtained. About 4 grams of potassium iodide and 10 c.c. of 80 per cent. acetic acid were added, and the flask shaken for 10 minutes. The solution was then titrated with thiosulphate as usual. The results given are less than 93 per cent. too low.—F. S. N.

Cobalt and Nickel: Electrolytic Analysis of — (F. M. Perkin and W. C. Prebble. Paper read before the Faraday Soc., Dec. 19, 1904).

The following method yields firm, bright deposits, and gives analytically correct results:—One gram of cobalt ammonium sulphate is dissolved in 50 c.c. of water and 5 c.c. of a 5 per cent. solution of phosphoric acid are added. After a further addition of 25 c.c. of a 10 per cent. solution of sodium dihydrogen phosphate, the liquid is made up to 130 c.c. and electrolysed. A brown deposit of cobalt oxide forms on the anode after half an hour or so, and this is dissolved away by adding about 0.5 gram of hydroxylamine sulphate or chloride. When the bulk of the cobalt has been deposited, it is advantageous to add a few drops of dilute ammonia to neutralise the excess of electrolytically liberated acid. At a temperature of 55°–60° C., electrolysis is complete after 3½ hours, the current density being kept low for the first hour (0.4 ampere per sq. dm.), and then raised to 1.1–1.8 amperes. Whereas this phosphoric acid bath was found to be the only one suitable for cobalt, nickel which deposits well from several other baths gave unsatisfactory results from it.—W. A. C.

ORGANIC—QUALITATIVE.

Sumach: Detection of Adulterants in —, by Microscopical Examination. (M. C. Lamb, *J. Soc. Dyers and Colourists*, 1904, 20, 265—268).

A METHOD for the detection of adulterants in sumach by means of the microscopical examination of their leaf cuticles has been previously published by the author (this J., 1899, 403), the method now given is for the examination of sumach in powder form.

One or two grams of the sample to be tested, are heated with nitric acid (1 : 1) until nitrous acid fumes are evolved, the mixture is allowed to stand for 15 to 30 minutes, and then again heated until the solution becomes clear. The liquid is diluted and filtered; the small particles of leaf cuticle remaining on the filter are removed and coloured by treatment with a weak solution of some suitable dyestuff, e.g., Bismarck Brown, Safranin, Methylene Green. The dyed particles are washed and afterwards transferred to a glass-slip for microscopical examination.

The characteristic features of the cuticle of pure sumach when examined with a 1-inch objective, are the hairs which have the appearance of pin-like bodies, and the stomata, consisting of small elliptical openings, surrounded by "guard" cells.

Illustrations taken from photomicrographs of samples of ground sumach adulterated with the two most common adulterants, *Pistacia Lentiscus* and *Tamarix Africana*, are shown in the paper; no hairs appear on the cuticles of either of these leaves. The stomata of the lower cuticle of *Pistacia Lentiscus* are larger and more numerous than those of sumach, whilst the cells are nearly all hexagonal in shape. *Tamarix Africana* leaves possess polygonal cells and very few stomata.

By treatment with nitric acid, pure sumach almost completely dissolves, leaving a sumach "wreck"; the adulterants, however, are unaffected by the treatment.

A "sumach" tanned leather may sometimes be examined for adulteration with *Pistacia* or *Tamarix* by the same method, the leather during the tanning usually becoming impregnated with minute particles of the sumach and adulterants. The leather is first dissolved in caustic soda, and the cuticles prepared by treatment with nitric acid in the same manner as when dealing with sumach.—M. C. L.

Fructose: Methylphenylhydrazine Reaction of —. (C. Neuberg, *Ber.*, 1904, 37, 4616—4618).

ALTHOUGH it is possible to prepare dextrose-methylphenyl-osazone from dextrose and methylphenylhydrazine (see Ofner, this J., 1904, 993), yet, under the conditions given by the author (this J., 1902, 506 and 1103), the formation of this compound may be used as a test for the presence of levulose. Under these latter conditions, dextrose yields only the methylphenylhydrazone. The preparation of the osazone from dextrose is possibly preceded by the conversion of the dextrose into levulose, a change which is known to be brought about not only by alkali, but also by acetates, neutral salts or phenylhydrazine itself.

—T. H. P.

Sugars; Action of Secondary Asymmetric Hydrazines on —. First Communication. R. Olier. *Monatsh. f. Chem.*, 1904, 25, 1153–1163.

Benzylphenylhydrazine.—Although commercial benzylphenylhydrazine gives small quantities of osazone, both with dextrose and fructose, this reaction is attributable to the presence of phenylhydrazine, as a decomposition product, in the reagent. The purified benzylphenylhydrazine gives no crystalline osazone. When phenylhydrazine is purposely added to the pure benzylphenylhydrazine an osazone, previously erroneously regarded as the benzylphenylosazone, is obtained in satisfactory yields, both with fructose and dextrose. This osazone, which melts at 190° C., is in reality the phenyl-benzylphenylosazone of dextrose or fructose. The same primary, secondary, or "mixed" osazone is also obtained by heating phenyldextrosazone with an excess of benzylphenylhydrazine.

Methylphenylhydrazine.—The same methylphenylosazone, melting at 153° C., is obtained both from dextrose and fructose, though the latter sugar reacts more easily than the former. When the methylphenylhydrazine is contaminated, either by decomposition or intentionally, with phenylhydrazine, a "mixed" phenyl-methylphenylosazone, melting at 192–195° C., is produced (see also this J., 1904, 883 and 993). The author concludes that the secondary asymmetric hydrazines are not to be relied on for the separation of ketoses from aldoses.—J. F. B.

Milk Sugar and Maltose; New Colour Reaction for —. A. Wöhik. *Z. anal. Chem.*, 1904, 43, 670–679.

The test is carried out in the following manner:—0.7–0.5 grm. of milk sugar is dissolved in a narrow test-tube in 10 c.c. of 10 per cent. ammonia, and the tube is heated in a water-bath, near the boiling point, in such a manner that the ammonia evaporates gradually. After 15 or 20 minutes a very characteristic madder-red coloration is developed, which is permanent towards light, but gradually turning brown in presence of air.

A large number of carbohydrates and sugars were tested by the author in the same way, but, with the exception of milk sugar and maltose, none of them gave the red coloration. This reaction serves for the detection of milk sugar or maltose in mixtures of carbohydrates, provided either of them is present in such quantities that the red coloration is not masked by the yellow or brown colour produced by the other bodies.

The presence of certain salts, such as tartrates, ammonium sulphate, ammonium chloride, &c., interferes with the reaction, and in many cases it is necessary to isolate the sugar before applying the test. It is suggested that this reaction might form a basis for the colorimetric determination of milk sugar in milk.—J. F. B.

Milk; Use of Methylene Blue to Distinguish Cooked Milk from Raw —. Schardinger. *Nouv. Remèdes*, 19, 229. *Pharm. J.*, 1904, 73, 815.

TWENTY c.c. of the milk are heated for 10 minutes at 40°–45° C., with 1 c.c. of a reagent containing 5 c.c. of an alcoholic solution of Methylene Blue, 5 c.c. of formalin, and 190 c.c. of water. Fresh raw milk completely decolorises the reagent, but boiled milk is without action upon it. If the milk be sour, it must be made neutral or alkaline before applying the test, as acid milk, whether raw or cooked, decolorises the reagent.—A. S.

ORGANIC—QUANTITATIVE.

Kjeldahl Nitrogen Determinations; Influence of Different Kinds of Glass on the Accuracy of —. H. Schönewald and K. Bartelt. *Woch. f. Brau.*, 1904, 21, 793–791.

By making a series of distillations of ammonia from pure ammonium chloride, in quantities corresponding to those generally employed in the determination of albuminoids by Kjeldahl's method, the authors have proved that the errors involved in the use of apparatus made of ordinary soft Thuringian [soda] glass are very considerable, but that Jena "thermometer glass 16 III." gives very

satisfactory results. The magnitude of the error is proportional to the quantity of ammonia distilled. It makes no practical difference whether the condenser be cooled by air or by water-circulation. The error is caused by the solvent action of the ammoniacal steam on condensed water upon the alkalis of the glass; pure steam has no noticeable corrosive action even on soft glass.—J. F. B.

Caoutchouc and Gutta-Percha; Assay of —. W. Esch and A. Chwolson. *Chem. Zeit.*, 1904, 28, 1195–1196.

The caoutchouc, &c., is rolled into a thin sheet, over-heating being carefully avoided. A weighed quantity is twisted loosely, between layers of thick filter-paper, into a spiral, which is closed at each end by extraction thimbles; it is then subjected to extraction by acetone in a Soxhlet apparatus. The resin having thus been determined, the caoutchouc is dissolved out of the residue by toluene vapour in a Pontio's "digesteur-lixivateur." The residue remaining after this treatment is free from caoutchouc.—W. A. C.

Beetroot Juice; Determination of Reducing Sugars in —. H. and L. Pellet. *Bull. Assoc. Chim. Sucri. Dist.*, 1904, 22, 374–378.

From 20 to 50 c.c. of Fehling solution are used with an equal volume of the liquor used direct, but diluted where qualitative tests show the necessity, so as not to contain more than .02 to .03 per cent. of reducing sugars. The mixture is heated in a bath of boiling water to 85–87° C., and the heat maintained 3 minutes longer. 20 to 50 c.c. of cold water are added, and the solution filtered through paper free from ash. The precipitate is washed with boiling water until the washings are neutral, calcined in a muffle and weighed as cupric oxide. From this weight, a deduction is made for the saline matter retained by the paper. A blank experiment usually gives 5 to 7 mgrms. The reducing sugar is calculated by multiplying the weight of cupric oxide by 0.453. It is advisable to check the copper by titrating with stannous chloride where the percentage of reducing bodies is high, as in cane-sugar products, and to confirm the results by parallel tests on known quantities of added invert sugar. Turbid liquids that will not filter clear are defecated with neutral acetate of lead. The lead must not be removed by sodium carbonate. If the liquid is clear, but contains sufficient lime salts to interfere with the precipitation of cuprous oxide, sodium carbonate may be used, avoiding excess. When neutral lead acetate has been used, the precipitate must be ignited in a porcelain crucible, otherwise platinum may be used.—L. J. DE W.

Molasses containing Reducing Sugars; Analysis of Refinery —. H. Pellet. *Bull. Assoc. Chim. Sucri. Dist.*, 1904, 22, 373–374.

The procedure indicated by the author (this J., 1904, 1047) for the determination of crystallisable sugar, reducing sugars and dry solids is applicable to the analysis of refinery molasses resulting from working up beetroot sugars more or less mixed with cane sugars, pure cane sugars, or products from candy works. With increase of reducing bodies, the quantity of ash diminishes notably. The nature of the reducing sugars will, however, not be the same as in cane sugars unless these also have been changed by prolonged heating to a high temperature. Although it may happen that direct polarisation gives the true amount of sucrose present, it is indispensable to check this in every case by polarisation before and after inversion.

—L. J. DE W.

Barley; Direct Determination of Extract in —. G. Merz. *XVII.*, page 38.

Fat in Butter; Determination of —. A. Hesse. *Z. Untersuch. Nahr. u. Genussm.*, 1904, 8, 673–675.

From 1½ to 2 grms. of the well mixed butter are introduced into a stoppered cylinder, and melted by the addition of about 8 c.c. of hot water. One c.c. of ammonia and 10 c.c. of alcohol are added and shaken up with the butter until the albuminoids are dissolved. After cooling, the mixture is shaken with 25 c.c. of ether, and again after

of 25 c.c. of petroleum spirit. The clear etheral layer is pipetted off and 50 c.c. of ether is added and the mixture allowed to settle. Finally 50 c.c. of ether is added and the petroleum spirit is again pipetted off. The clear supernatant layer again pipetted off. The united etheral layers are evaporated and the fatty residue weighed. It is claimed that this method settles the presence of fatty matters in the extract. It is claimed to be superior to the other methods in use.

W. A. C.

XXIV. SCIENTIFIC & TECHNICAL NOTES.

Attractive Force of Crystals for Lavoisier's Experiment. — E. Soustardt. Chem. Soc. Proc., 1904, 20, 244-245.

SATURATED solutions of various salts were prepared in pairs, and to one of each pair were added crystals of the dissolved salt. The solutions were then kept for some time in a cellar, the temperature of which remained almost constant. It was found that the added crystals removed from solution a certain quantity of the dissolved salt. — A. S.

Oxidation Phenomena; Some. — G. Kassner. Z. angew. Chem., 1904, 17, 1851-1856.

THE author reviews the work which has been done on the subject of autoxidation and the formation of "hologides" or peroxides. He concludes that there are five general modes of formation of hologides or peroxides:—(1) By the union of molecular oxygen to oxidisable substances in the process of autoxidation, and in the oxidation of certain metals (barium, alkali metals, &c.) at high temperatures. (2) By union of negative ions of oxygenated acids during electrolysis. (3) By decomposition of the ozonides discovered by Harries. (4) In the case of thorium and zirconium, by Pissarjewsky's synthetical method by means of hypochlorites. (5) By transformation of compounds containing labile oxygen atoms; this has up to the present only been observed in the case of the higher oxygenated compounds of lead. (See also this J., 1897, 941; 1898, 387, 579, 1194; 1899, 65, 1124; 1900, 172, 278, 682, 697; 1901, 578, 841, 929, 1151; 1902, 257, 720, 1301; 1903, 969, 1121, 1155.) — A. S.

Electro-positive Metals; Action of same on Potassium Iodide. — F. Streintz. Physik. Zeits., 1904, 5, 736-737. Chem. Centr., 1904, 2, 1530.

THE action of metals on photographic plates and on potassium iodide paper, observed by Blaas and Czerniak (Physik. Zeits., 5, 363), is explained by the author as an effect due to Nernst's electrolytic solution-pressure; the positive ions discharged from the metal exert an ionising action on the silver salt of the photographic plate, or on the potassium iodide, this action being greater the more electro-positive the metal. Polished magnesium has a much stronger action on potassium iodide paper than zinc, whilst the latter is more active than cobalt. Perfectly bright aluminium has a very strong action on potassium iodide. Magnalium (an alloy of magnesium and aluminium) is more active than magnesium; iron, tin, lead, nickel, copper, mercury, silver, gold and platinum are inactive. If cells of high E.M.F. be constructed (e.g., zinc-glycerin solution soot), these act strongly, whilst cells of small E.M.F. (e.g., magnesium-zinc) have scarcely any action. The rays will penetrate paper, but not mica, glass or tinfoil. — A. S.

Mercuric Chloride Solutions; Action of Acetylene on. — K. A. Hofmann. Ber., 1904, 37, 4459-4460.

IT has been previously shown (this J., 1898, 1078; 1899, 79) that the white crystalline precipitate obtained by acting with acetylene gas on aqueous solutions of mercuric nitrate, is, according to the conditions, either di- or trimercuraldehyde. If acetylene gas be passed through an ice-cold solution of equimolecular proportions of mercuric and sodium chlorides, a precipitate is produced which, after being washed with ice-cold water and dried by means of alcohol and ether, gives the reactions of

trichloromercuraldehyde $(\text{CH}_2)_3\text{CCHO}$, but contains more chlorine than that compound. This is probably due to the formation of the compound $\text{C}_3\text{Hg}_3\text{Cl}_4$ as an intermediate product, from which the trichloromercuraldehyde is produced by hydrolysis. In presence of an excess of sodium chloride, acetylene does not produce any precipitation in mercuric chloride solution. From solutions of mercuric chloride free from sodium chloride, nearly pure trichloromercuraldehyde is precipitated by acetylene.

— A. S.

Organo-Magnesium Compounds; New Method of Preparing. — (Grignard's Reaction.) W. Tschelinzoff. Ber., 1904, 37, 4534-4540.

THE product of the reaction of magnesium on alkyl or aryl halides in etheral solution was looked on by Grignard as being, not R.MgH , but $\text{R.MgH.R}_2\text{O}$; and Baeyer and Villiger regard this substance as an oxonium compound. The author considered that the function of the ether was probably to loosen the bond between radical and halogen in the haloid compound; and that view is confirmed by the fact that the reaction takes place in a benzene solution, if a small quantity of ether be added. Brühl and Oerdt, and also Malmgren, have stated that the reaction occurs in benzene solution even without the presence of ether; the author finds that to be the case only at the high temperature (that of boiling xylene) at which those investigators worked. Ether acts in this reaction as a true catalyst; it causes the reaction to take place easily at the ordinary temperature, or a little above it, and a very small amount of ether is enough for the production of a large amount of halide. The stages of the reaction appear to be

The author had previously shewn that tertiary amines could be substituted for ether in Grignard's reaction. He now finds that these amines also act catalytically, and with greater vigour than ether; using $\frac{1}{2}$ gram-molecule of benzaldehyde with equivalent amounts of ethyl iodide and magnesium, and $\frac{1}{100}$ gram-molecule of dimethylaniline, the whole in benzene solution, an 82 per cent. yield of ethyl-phenyl-carbinol was obtained; and a 63 per cent. yield of diphenylcarbinol when phenyl iodide was substituted for ethyl iodide. To carry out the process in practice, the reaction-mixture in pure dry benzene is heated on a water-bath till the benzene boils (unless reaction, shewn by the deposition of white flocks, begins earlier; sometimes the addition of a crystal of iodine will hasten its beginning); the mixture is then removed from the bath till reaction ceases, cooling if necessary, and finally heated again to carry the reaction to an end. The author has as yet used only dimethylaniline; but possibly the nature of the amine may have an influence on the progress of the reaction. — J. T. D.

New Books

YEAR-BOOK OF PHARMACY, COMPRISING ABSTRACTS OF PAPERS RELATING TO PHARMACY, MATERIA MEDICA, AND CHEMISTRY, contributed to British and Foreign Journals from July 1, 1903, to June 30, 1904, with the Transactions of the British Pharmaceutical Conference at the 41st Annual Meeting held in Sheffield, August, 1904. J. O. BRAITHWAITE, E. SAVILE PECK, and EDMUND WHITE, J. and A. Churchill, 7, Great Marlborough Street, 1904. Price 10s. 6d.

SUBJECT-LIST OF WORKS ON THE FINE AND GRAPHIC ARTS [INCLUDING PHOTOGRAPHY], AND ART INDUSTRIES IN THE LIBRARY OF THE PATENT OFFICE. Darling and Son, Ltd., 34-39, Bacon Street, London, E. Patent Office, 25, Southampton Buildings, Chancery Lane, W.C., 1904. Price 6d.

Die Industrie der Essigsäure und der Essigsäueren Salze. Von Dr. S. MIERZINSKI. Carl Scholtz (W. Junghans), Leipzig, 1905. Price M.4.50.

Svo volume, containing preface, subject matter filling 209 pages, and illustrated by 38 engravings, and an alphabetical index of subjects. The work commences with (1) A Theoretical Introduction; (2) The Manufacture of Acetic Acid; (3) The Acetates; (4) Acetic Ether (Ester), and (5) Acetone. An alphabetical index of subjects forms the conclusion.

THE SPINNING AND TWISTING OF LONG VEGETABLE FIBRES (Flax, Hemp, Jute, Tow and Ramie): A Practical Manual of the Most Modern Methods as applied to the Hackling, Carding, Preparing, Spinning and Twisting of the Long Vegetable Fibres of Commerce. By HERBERT R. CARTER. Charles Griffin and Co., Ltd., Exeter Street, Strand, London, 1904. Price 16s.

Svo volume, containing 353 pages of subject matter, with 161 illustrations, including 10 plates, and an alphabetical index of subjects. The leading themes are as follows:— I. The Long Vegetable Fibres of Commerce. II. Rise and Growth of the Spinning Industry. III. The Raw Fibre Markets and the Purchase of the Raw Material. IV. Storing the Raw Materials, and the Preliminary Operations of Batching, Softening, Knitting, Roughing, Breaking and Cutting. V. Hackling (hand and machine). VI. Sorting. VII. Preparing—Sliver formation. VIII. Tow Carding and Mixing. IX. Preparing, Drawing and Doubling, and Tow Combing. X. Gill Spinning. XI. Flax, Hemp, Jute and Ramie Roving Frame. XII. Their Dry and Demi-Sec. Spinning. XIII. Wet Spinning. XIV. Waste Spinning. XV. Yarn Reeling, Winding, Drying, Cooling and Bundling. XVI. Manufacture of Threads, Twines and Cords from Flax, Hemp, Jute and Ramie Yarns. XVII. Rope Making. XVIII. The Mechanical Department. XIX. Modern Mill Construction. XX. Boilers and Engines, Steam and Water Power. XXI. Power Transmission.

INKS; THEIR COMPOSITION AND MANUFACTURE, INCLUDING METHODS OF EXAMINATION AND A FULL LIST OF ENGLISH PATENTS. By C. AINSWORTH MITCHELL, B.A., and T. C. HEWORTH. Charles Griffin and Co., Ltd., Exeter Street, Strand. 1904. Price 7s. 6d.

SMALL Svo volume, containing preface and 242 pages of subject matter with 46 illustrations, including 4 plates. There is an alphabetical index of subjects. The chapters are subdivided as follows:—Historical Introduction. SECTION I. WRITING INKS. (i) Carbon and Carbonaceous Inks; (ii) Tannin Materials for Inks; (iii) Nature of Inks; (iv) Making Iron Gall Inks; (v) Logwood, Vanadium and Aniline Black Inks; (vi) Coloured Writing Inks; (vii) Examination of Writing Inks. SECTION II. PRINTING INKS. (i) Early Methods of Making; (ii) Manufacture of Varnish; (iii) Preparation and Incorporation of the Pigment; (iv) Coloured Printing Inks. SECTION III. INKS FOR MISCELLANEOUS PURPOSES. (i) Copying Inks; (ii) Marking Inks; (iii) Safety Inks and Papers; (iv) Sympathetic Inks; (v) Inks for Special Purposes; (vi) List of British Patents.

THEORETICAL CHEMISTRY FROM THE STANDPOINT OF AVOGADRO'S RULE AND THERMODYNAMICS. By Prof. WALTER NERNST, Ph.D., of the University of Göttingen. Revised in Accordance with the 4th German Edition. Macmillan and Co., Ltd., London, 1904. Price 15s. The Macmillan Co., New York.

Svo volume, containing 756 pages of subject matter, with 35 illustrations, and an alphabetical index of subjects and authors. The leading themes are as follows:— I. Introduction to Some Fundamental Principles of Modern Investigation. II. The Universal Properties of Matter. III. Atom and Molecule. IV. The Transformation of Matter (Doctrine of Affinity, i.). V. The Transformation of Energy (Doctrine of Affinity, ii.). In this latter (V.) are included chapters on (i.) Thermochemistry, (ii.) Electrochemistry, and (iii.) Photochemistry.

Trade Report.

I. GENERAL.

CHEMICAL INDUSTRIES: DISTRIBUTION OF PERSONS ENGAGED IN — THROUGHOUT THE CHIEF COUNTRIES OF THE WORLD.

British and Foreign Trade and Industry, Memoranda, Statistical Tables and Charts, Second Series, prepared in the Board of Trade. Vol. 2337. Dec., 1904. Pp. 431—566.

The following figures show the changes which have taken place in a period of 20 years in the proportions of population engaged in the leather, paper, glass, pottery, and chemical trades, the numbers being "persons per 10,000":—United Kingdom, 1881, 160; 1901, 166, Germany, 1875, 178; 1895, 213. United States, 1880, 79; 1900, 96. The figures for the United Kingdom are taken from the Census Reports for 1901.

The *Leather Trades* statistics show that 9,608 persons were employed in England and Wales as tanners in 1901, 967 in Scotland, and 167 in Ireland; total, 10,742. In Russia, 28,180 persons were engaged in the industry in 1897; in Sweden, 2,376 in 1896, and 2,326 in 1901; in Denmark, 1,375 in 1897; in Holland, 2,545 in 1889, and 2,628 in 1899; Belgium, 6,938 in 1896. In the German Empire (includes currying, varnishing, &c., and parchment manufacture), 45,637 in 1882, and 53,946 in 1895. In France, in 1896, 1,600 persons were engaged in skin dressing and dyeing, 9,500 in tawing, and 20,200 in tanning. 821 persons were employed in tanning in Switzerland in 1901. In the United States 56,024 persons were engaged in manufacturing "leather-tanned, curried and finished (including dressed skins)."

Paper Trades.—In 1901, 34,357 persons were employed in paper manufacture in the United Kingdom in 1901. In Russia in 1897, 487 persons manufactured wood pulp, 1,562 wall paper and coloured paper, and 21,528 other kinds of paper. In Sweden, 7,400 persons were engaged in making wood pulp in 1901, and 6,078 in paper manufacture. In the German Empire the paper industry gave employment to 85,104 persons in 1895, as compared with 58,060 in 1882. In Belgium, there were 9,448 workers in 1896, and in France 23,690, of whom 3,469 manufactured coloured paper. In 1901, there were 2,129 paper makers in Switzerland, and 20,257 in Italy. In 1902, 5,026 Japanese were engaged in paper making. Paper and wood pulp mills in the United States gave employment to 53,012 persons in 1900. The total number engaged in all paper trades was 72,159.

Glass Industry.—In Great Britain 32,929 persons were engaged in the glass industry in 1901, as against 28,568 in 1891. Other countries employed the following numbers (the year of census being given in brackets):—Russian Empire (1897), 36,193; Sweden (1901), 5723; Denmark (1897), 1117; German Empire (1895), 58,221; Holland (1899), 3,325; Belgium (1896), 22,797; France (1896), 21,428; Switzerland (1901), 816; Italy (1901), 8,039; Austria (1900), 43,069; Hungary (1898), 4,545; United States (1900), 61,164.

Brick, Tile, and Pottery Industries.—The following figures give the numbers employed in the years indicated:—Great Britain (1901) 135,618, (1891) 109,173; Russian Empire (1897), 88,303; Sweden (1901), 13,204; Denmark (1897), 10,044; German Empire (1895), 306,919; Holland (1899), 6,773; France (1896), 80,100; Switzerland (1901), 6,870; Italy (1901), 37,203; Austria (1900), 57,255; Hungary (1898), 23,591; United States (1900), 122,277.

Chemical Trades.—In Great Britain and Ireland the total number employed in 1901 was 58,232. Included in these figures are dye, paint, ink and blacking, 7,533; explosives and matches, 15,010; manufacturing chemists, 20,444; alkali manufacturers, 9,857; manure manufacturers, 1,991; glue, size, varnish, &c., makers, 3,397. The total figure shows an increase of 17,271 on that of 1891. In Germany, in 1895, the total number engaged was

97,470, compared with 57,388 in 1882. The following classification is adopted:—

	1882	1895.
Chemical works	14,910	26,951
Chemical, pharmaceutical and photographic preparations	8,463	12,699
Aniline and other dyes	4,197	5,266
Coal-tar products other than above	547	4,194
Essential oils and perfumes	1,389	2,162
Colours and dyes except aniline and other		
Coal-tar dyes	9,909	10,786
Explosives	5,733	16,516
Match-sticks and other kindling materials	4,951	6,893
Artificial fertilisers	5,078	8,014

In the United States, 140,515 persons were employed in chemical industry in 1900, compared with 78,204 in 1890. The following figures are given for 1900:—Chemicals, 21,419; perfumery, cosmetics and essential oils, 3,182; dyestuffs and extracts, 1,937; turpentine and resin, 45,945; ink, 1,283; pigments and paints, 11,079; varnishes, 2,863; fertilisers, 13,654; explosives and fireworks, 7,106; matches, 2,120.

Other countries had the following numbers of persons engaged in various chemical industries:—Russian Empire (1897), 32,414; Sweden (1901), 9,488; Denmark (1897), 1938; Holland (1899), 2,607; Belgium (1896), 11,956; France (1896), 42,900; Switzerland (1901), 4,385; Italy (1901), 15,958; Austria (1890), 13,313; Hungary (1898), 7,943.

SWITZERLAND: TRADE OF — IN 1903.

Foreign Office Annual Series, No. 3314.

The total imports of druggists' sundries, chemicals and colouring materials in 1903 amounted to £1,647,000 (an increase of £109,000 on the imports of 1902), of which £1,469,000 was for manufactured chemical products. The imports from the United Kingdom amounted to £59,500. The imports under this heading show year by year an upward tendency, but last year the auxiliary materials and the manufactures principally accounted for the increase of upwards of £100,000. The imports from all countries, together with the share of the United Kingdom, included the following:—

Articles.	From—	
	All Countries.	United Kingdom.
	£	£
Drugs	94,600	2,000
Alkaloids	26,300	1,400
Pharmaceutical preparations	43,300	5,000
Aniline oil and aniline compounds	71,800	1,300
Stearine	34,800	4,500
Gelatin and fish-glue	8,200	1,000
Varnishes	33,900	9,600
Anthracene, benzoic acid, benzene, carbolic acid, &c.	81,700	1,500
Colouring materials	264,000	1,600
Perfumed soaps	10,200	1,120

* Includes aniline dyestuffs £61,820 and £710 respectively.

The total imports of oils, soaps, and fats in 1903 amounted to £591,400, of which the United Kingdom supplied £24,500, or £2,000 more than in 1902. The principal articles imported from all countries and from the United Kingdom were as follows:—Various liquid greases and oils, £206,000 (from the United Kingdom, £20,000); candles, £25,000 (United Kingdom, £600); ordinary and scented soaps, £42,700 (United Kingdom, £1,500).

The value of the total imports of linoleum was £76,600, an increase of £13,000 on the imports in 1902. The imports from the United Kingdom amounted to £33,500, being an increase of nearly £4,000 on the imports of last year. The imports from Germany amounted to £12,000.

The increase in the demand for linoleum in Switzerland has been rapid, as will be seen from the following figures:—

Year.	Imports.	
	Total.	From United Kingdom.
	Cwts.	Cwts.
1890	4,683	..
1895	8,884	..
1900	24,225	13,789
1902	26,080	12,206
1903	31,340	13,720

* Not given.

The total imports of varnishes in 1903 amounted to £33,900 (an increase of £3,600 on 1902), of which the United Kingdom supplied £9,600. The principal supply came from Germany, representing a value of £16,000.

Exports of "chemicals" from Switzerland in 1903 reached a total value of £1,357,800, of which £150,000 worth went to the United Kingdom.

PATENT LAWS IN SWITZERLAND: PROPOSED AMENDMENT OF —.

Chem. and Druggist, Dec. 24, 1904.

The Swiss Government proposes to extend patent protection to chemical products, and it is understood that the opponents of the proposed extension in Switzerland are at present the colour-works industry, the industries which utilise these products, and pharmaceutical chemists. The Soc. pour l'Industrie Chimique à Basle is in favour of the suggested legislation if the utilising industries are excepted from its scope. The Government says that if the proposed law is not in force by December 31, 1907, Germany will tax Swiss dyes imported into that country.

CUBA: IMPORTS OF DRUGS AND CHEMICALS, INCLUDING OILS AND PAINTS INTO —.

Foreign Office Annual Series, No. 3315.

British manufactures represent only 8 per cent of the total imports of these products.

The United Kingdom supplies 15 per cent. of the opium, 35 per cent. of the paints and colours, 25 per cent. of the chemical products, 45 per cent. of the vegetable oils (such as linseed but not counting olive oil) and 21 per cent. of the mineral waters. The United Kingdom has little or no share in the importation of varnishes, medicines and pharmaceutical preparations, candles, soap, or perfumery, the consumption of which in the aggregate represents over £300,000 a year.

VII.—ACIDS, ALKALIS, Etc.

MAGNESITE IN THE TRANSVAAL.

Eng. and Mining J., Dec. 8, 1904.

In the expectation that the deposit of magnesite recently discovered in the Barberton district will yield profitably, a company with £200,000 capital has been formed at Pretoria to work it. According to the analyses of the engineer, the mineral carries an average of 46.44 per cent. magnesia, and 49.66 per cent. carbonic acid, which is nearly the same as the Grecian magnesite. Development work has proved the existence of a large vein of good mineral. The inauguration of this new industry in the Transvaal will show whether or not a low-priced mineral, paying a heavy ocean freight, can be marketed at a profit.

VIII.—GLASS, POTTERY AND EARTHENWARE.

CORUNDUM DISCOVERY IN CANADA.

U.S. Cons. Rep., No. 2124, Dec. 5, 1904.

A rich deposit of corundum has been found on a farm in Methuen Township, county of Peterboro. A sample

f the deposit was assayed by the government geological survey, and pronounced very rich. Its specific gravity is 3.99, while that of good corundum is 3.85. The value of the mineral is placed at \$390 per ton. The feldspar in which the corundum is found is also very valuable.

X.—METALLURGY.

RARE MINERALS IN AUSTRALIA.

Eng. and Mining J., Dec. 8, 1904.

Two of the principal ores of tungsten (wolfram and scheelite) occur in several localities in Western Australia. According to the assistant government geologist, wolfram occurs in small quantities near Roebourne, and in other parts of the Pilbarra district, and also in the Geraldton district. Scheelite has been found in small quantities in Fraser's mine, Southern Cross; Lindsay's mine, Coolgardie, and Hannan's Hill, Kalgoorlie. Its occurrence has also been noted in association with the tin of Greenbushes. There is no record of the minerals having been obtained commercially in any of these instances, but, as far as can be judged at present, the occurrence of wolfram in the Pilbarra district seems to hold out the best chances for investigation.

In North Queensland, the principal source of tungsten in Australia, the majority of the producing claims lie along a fairly continuous reef of quartz, the granite for some distance on either side being intersected by an irregular system of smaller quartz veins and offshoots, from which the wolfram is chiefly obtained. The output of the Queensland fields from 1894 to the end of 1903 is estimated at 947.5 tons. About the middle of last year wolfram was selling on the field in North Queensland at £29 per ton, and at the end of 1903 it was £50, since which time it has risen to £140. It is there chiefly purchased by agents, who visit the field. The demand for wolfram is comparatively small and somewhat irregular, and any large output would demoralise the market.

Molybdenite, containing when pure 60 per cent. of metal, occurs in Queensland, and in Western Australia, at Clackline, Coolgardie, Southern Cross and Buldania. In 1903, Queensland produced 11 tons, valued at £1,321.

Occurrences of vanadinite (chloro-vanadate of lead) have been recorded in Western Australia at Mulline (North Coolgardie), Pinyalling (Yalgoo) and Coolgardie. Uranium minerals have not so far been noted in Western Australia.

MINERAL RESOURCES OF CANADA.

Board of Trade J., Dec. 22, 1904.

In a recent issue, the *Monetary Times* (Toronto), alluding to the mineral resources of the Lake St. John region, north of Roberval, Quebec, says that recent explorations show that this part of the country is likely to yield large quantities of gold, copper and asbestos. Last year rich beds of asbestos, copper and gold quartz were found in the neighbourhood of Lake Chabugamoee. Some samples of gold quartz and copper show that the former will yield 64 dols. to the ton, and the latter 53 dols. The breadth of the vein is said to be 30 feet, with a depth of 2,000 feet. Vast quantities of iron ore are also said to exist in the same vicinity, some mounds of iron ore being 200 feet high. A company has been formed to develop these and any other mineral areas which may be discovered.

According to a report by the Ontario Bureau of Mines, important deposits of high-grade hematite have been discovered in the lower levels of the Williams iron mine on the Algoma Central Railway. This is an entirely new iron area, and if the deposits prove to be continuous, may develop into an important field. North of Temagami, there are two promising prospects, one for iron pyrites and the other for arsenical pyrites. There are also a number of other iron pyrites and arsenical properties in the district.

PORTUGAL; MINERAL PRODUCTION OF—

Eng. and Mining J., Dec. 8, 1904.

Subjoined is a detailed statement of the mineral output in the Kingdom of Portugal during the year 1903. Com-

pared with the figures for 1902, all the important items show a marked decrease, as given below, in metric tons.

	1902.	1903.
Anthracite	11,000	8,000
Cupiferous iron pyrites	413,714	376,177
Gold ore	kg 2,261	1,361
Iron ore	19,914	15,200
Lead ore	1,651	830

Other products of less magnitude were, in metric tons: White arsenic, 698; copper precipitate, 2,448; copper pyrites, 527; gold and antimony concentrate, 83; manganese ore, 30; wolfram, 228; zinc, copper and lead ore, 1,974. The mineral output for the year has an estimated value of £117,000 in all.

The whole number of persons employed in and around mines was 4,547, of whom 192 were females working above ground. Four fatalities occurred during the year.

IRON AND STEEL INDUSTRY OF SOUTHERN RUSSIA.

Board of Trade J., Dec. 29, 1904.

The iron and steel foundries of Southern Russia, during the year ended 30th June, 1904, produced 100,600,000 pounds of pig iron (an increase of 30.55 per cent.); 85,729 pounds of ingots (an increase of 21.5 per cent.), and 72,257,000 pounds of finished iron and steel (an increase of 25.87 per cent.).

The output of iron ore from Krivoy-Rog and Kertch during the same period amounted to 176,844,000 pounds (an increase of 32.6 per cent.); of manganese ore to 3,327,000 pounds (an increase of 30.1 per cent.).

XII.—FATTY OILS, FATS, Etc.

PALM OIL AND RUBBER IN FRENCH GUINEA.

Foreign Office Annual Series, No. 3313.

The export of palm oil and kernels from French Guinea increased from £20,280 to £24,104, the great bulk going to Germany where the market is more favourable. Sesame was exported to the value of £4,951, and groundnuts increased from £5,906 to £10,584. These two latter articles of export show that the efforts of the Government to induce the cultivation of other products are beginning to bear fruit, but the chief export of the colony continues to be rubber, which has almost doubled, having risen from £230,978 in 1902 to £455,551 in 1903, the United Kingdom taking £245,863, or more than the total export of the previous year. The rubber all comes from Upper Guinea and the Soudan, and has to be carried several hundred miles by hand to the coast.

OIL SEEDS AND SEED OILS IN FRANCE.

U.S. Cons. Rep., No. 2134, Dec. 16, 1904.

The imports of cotton-seed oil into France for consumption, from all countries, during 1903 were 21,606 tons, against 28,338 tons in 1902, a decrease of 6,732 tons, and a decrease of 20,994 tons from the imports of 1901. Of the receipts the United States furnished, in the three years named, 19,496 tons, 26,426 tons, and 40,456 tons, respectively; most of the remainder came from Great Britain.

The total imports, however, during the first eight months of 1904 from the United States, as well as from other countries, show an increase over the imports of the same periods of the two previous years; but the oil has not been consumed very freely, so that the quantities on which duties have been paid, and which have passed into consumption, are less than one year ago.

The imports of oleaginous seeds of all kinds into France in 1903 were the largest ever known. They reached a total of 827,000 tons, against 757,000 tons in 1902 and 677,000 tons in 1901. A slight falling off has taken place during the first eight months of 1904, the figures being 578,000 tons, against 618,000 tons in 1903 and 545,000 tons in 1902, but this decrease is not sufficient to offset

the unusual receipts of 1903, and the large stocks of all kinds of oils which are still on hand.

A feature in connection with the manufacture of vegetable oils in France is the falling off in the production of cotton-seed oil. The importations of cotton seed, notwithstanding the beautiful cotton crop in Egypt, amounted to only 30,000 tons in 1903, against 48,000 tons in 1902 and 45,000 tons in 1901; and in the first eight months of 1904 only 13,800 tons, against 25,000 tons in the first eight months of 1903 and 35,600 tons in the same period of 1902. The few French manufacturers who, in former days, made a specialty of high-grade cotton seed oils generally do not find it easy to compete with the fine grades of American oils. Besides, they are handicapped by the difficulty of disposing of their cake, which, unlike the American product, being in an undecorticated condition, does not find a ready sale to the French cattle feeder.

The last advices from India point to a somewhat reduced supply of oleaginous seeds from that country, but the stocks of all kinds of oil, both for edible and for manufacturing purposes, are so large that sellers are willing to contract for deliveries over the whole of next year at the present low prices.

The olive crops were abundant last season, and the production of olive oil exceeded the consumption to such an extent that large stocks have been carried over not only in France, but in all producing countries. The extreme heat and drought of the past summer are reported to have injured the prospects of the next crop, but with the abundance of oil on hand there seems to be but little danger of a scarcity during the coming season.

A bill for imposing duties on foreign oil seeds which are now on the free list, and increasing those on foreign oils, has been before the French Parliament for a long time. The committee has passed a vote in favour of a duty of 3 francs per 100 kilos, on colza seeds, and a corresponding duty, according to their yield in oil, on all other oleaginous seeds. At the same time the existing duties on vegetable oils, including cotton-seed oil, were raised to 12 francs per 100 kilograms. The duties on copra and palm kernels, as well as their oils, were not changed.

Shortly after this decision of the tariff committee Parliament adjourned, and the bill will be reported back to the tariff committee, and then sent up to the Chamber of Deputies for discussion during the present session. It will certainly meet with much opposition from the French oil manufacturers, whose interests are seriously menaced by it, from those who are engaged in the oil-seed trade with British India, and from the importers of American cotton-seed oil.

OLIVE-OIL OUTPUT OF SPAIN.

U.S. Cons. Rep., No. 2128, Dec. 9, 1904.

After two successive seasons of almost unprecedented yields of olives in Andalusia, the crop of this province and of the surrounding provinces has resumed ordinary proportions. There has been a corresponding falling off in the exportation of olive oil, though but 10 per cent. of a season's yield finds its way into foreign markets.

The crop of 1902 was the largest yield of the past decade, it being estimated that 40,000,000 arrobas (178,520,000 gallons) of oil were pressed in the provinces of Cordoba, Jaen, Seville, Granada, and Malaga. Dry weather during the period in 1903 when the olive was ripening caused much of the fruit to mature early and fall from the trees. In this manner a considerable amount of the crop was ruined, with the result that the quantity of oil pressed in the latter part of the year was approximately one-third less than that of the previous year. The exports to the United States for the nine months ended September 30, 1903 and 1904, have been as follows: 1903, 21,084 barrels, valued at \$494,633; 1904, 14,253 barrels, valued at \$323,387.

Prices vary but little from one year to another, £30 per ton being the usual figure. The olive oil exported from Malaga is of the class used for manufacturing purposes and never for table use.

It is anticipated that the coming crop, to be pressed in December, will be to some extent smaller than the past

one. Hot and dry weather, in excess of previous years, is given as the primary cause for this condition.

XIII. A.—PIGMENTS, PAINTS, Etc.

MINERAL PAINT PRODUCTION IN THE UNITED STATES.

U.S. Geological Survey, 1904.

The total production during 1903, consisting of metallic paint, ochre, umber, sienna, Venetian red, zinc white, slate graphite and carbonaceous shales and schists amounted to 126,649 short tons, valued at \$5,437,275, as compared with the production of 125,694 short tons, valued at \$4,960,831, in 1902. The increase in value is due to the increase in the production of the higher priced pigments.

Ochre, UMBER and SIENNA.—During 1903, the production of ochre in the United States amounted to 12,524 short tons, valued at \$111,625, as compared with the production in 1902 of 16,565 short tons, valued at \$145,708. The seven States contributing to this output in order of importance of production were Georgia, Pennsylvania, Arkansas, Iowa, California, Vermont and Virginia. Missouri and Illinois, which were numbered among the producers of ochre in 1902, reported no production during 1903.

Of the 1903 production, Georgia produced 41.6 per cent. of the total output, while Pennsylvania, which had the largest output, 59 per cent. in 1902, produced only 39 per cent. of the 1903 output. The production from Pennsylvania was 4,937 short tons, valued at \$34,782 in 1903, as against 9,818 short tons, valued at \$80,259 in 1902.

Pennsylvania was the only State reporting any production of umber or sienna during 1903. The combined production of these two mineral paints was 666 short tons, valued at \$15,367, as compared with 669 short tons, valued at \$15,546 in 1902. In 1902 there were three other States, Illinois, Georgia and New York, which reported a production of these mineral paints.

Metallic Paint.—The minerals used in the manufacture of metallic paint are hematite and limonite. Although these two minerals occur in a great many places in the United States, and in enormous deposits, the quantity of these ores that are suitable for making a good metallic paint is very small, and there are but a few localities that can furnish it.

The production of metallic paints in 1903 was obtained from Pennsylvania, New York, Ohio, Tennessee, Wisconsin, Alabama, Maryland, New Jersey and Virginia, named in the order of the importance of their production. The output amounted to 35,966 short tons, valued at \$314,901; the production in 1902 was 27,375 short tons, valued at \$412,119. Of the production of 1903, 25,103 tons, valued at \$213,109, was of metallic paint, exclusive of mortar colours, as compared with 19,020 short tons, valued at \$313,390 in 1902. The production of mortar colours in 1903 was 10,863 short tons, valued at \$101,792, as compared with 8,355 short tons, valued at \$98,729 in 1902.

Venetian Red.—During 1903 the production was 7425 short tons, valued at \$134,635, as compared with 11,758 short tons, valued at \$196,905 in 1902.

Slate Ground for Pigment.—Mineral black is the name applied to the product of the dark coloured slates and shales that are ground for paint, and in 1903 the total quantity of these materials that were used for this purpose amounted to 7,106 short tons, valued at \$59,029, as compared with the production of 4071 short tons, valued at \$39,401 in 1902. This does not include the production of the graphitic or carbonaceous shale or schist of Michigan, which is known as "Barafa graphite," nor the graphitic material obtained from Rhode Island. Both are used to some extent in the manufacture of graphite paints, as are also the purer forms of graphite from New York and Pennsylvania, the statistics of the production and value of which are included in those of graphite.

Lead Paints.—The lead pigments included here are white lead, sublimed lead, zinc lead, red lead, litharge and orange mineral. During 1903 the aggregate production of all lead pigments amounted to 141,486 short tons, valued at \$15,711,595, an increase of 18,095 short tons in quantity, and of \$3,058,810 in value, as compared with

the production of 123,391 short tons, valued at \$12,652,785 in 1902. The imports of these lead pigments in 1903 amounted to 1203 short tons, valued at \$103,312, as against 1334 short tons, valued at \$114,671 in 1902. This makes the total amount of lead pigments consumed in the United States in 1903 equal to 142,689 short tons, valued at \$15,814,907, as against 124,725 short tons, valued at \$12,767,456 in 1902.

White Lead.—The total production in 1903 amounted to 112,886 short tons, valued at \$12,837,647, as compared with the production of 114,658 short tons, valued at \$11,978,174 in 1902. Of the 1903 production, the quantity of white lead in oil was 62,671 short tons, valued at \$7,482,487, and the quantity of dry white lead and white oxide was 50,212 short tons, valued at \$5,355,160.

The import of white lead during 1903 amounted to only 227 short tons, valued at \$21,495, which indicates the gradual displacing of the imported pigments by those of domestic production.

Sublimed Lead.—Another lead pigment, known as sublimed lead, is obtained as a by-product in the oxidising smelting of galena ores; it consists essentially of lead sulphate and lead oxide. The output of this pigment in 1903 produced by the Picher Lead Co., of Joplin, Mo., amounted to 8,592,000 lbs., valued at \$386,640, as against 9,465,500 lbs., valued at \$449,611, in 1902.

Zinc Lead.—There is manufactured at Canyon, Cal., a product known as zinc lead, which consists of a mixture of zinc and lead oxides, obtained by an oxidising-smelting treatment of lead in zinc ores in a furnace of special design. The production of this pigment in 1903 amounted to 4500 short tons, valued at \$247,500, as against 4000 short tons, valued at \$225,000 in 1902, and 2500 short tons valued at \$150,000 in 1901.

Red Lead, Litharge and Orange Mineral.—The production of red lead during 1903 shows a considerable decrease from that of 1902, being 8832 short tons, valued at \$1,022,754, as compared with 11,669 short tons, valued at \$1,263,112 in 1902. The combined production of litharge and orange mineral during 1903 was 10,792 short tons, valued at \$1,217,054, as compared with 13,742 short tons, valued at \$1,437,692 in 1902.

There is still a considerable quantity of red lead and orange mineral imported into the United States, and in 1903 this amounted to 1,152,715 lbs. of red lead and 756,742 lbs. of orange mineral. Of the litharge, 42,756 lbs. were imported during 1903.

Zinc White.—The production of zinc white has increased steadily for the last ten years, and during 1903 it amounted to 62,962 short tons, valued at \$4,801,718, as compared with 52,730 short tons, valued at \$4,023,299 in 1902.

XIII. B.—RESINS, VARNISHES, Etc.

AMBER.

Eng. and Mining J., Dec. 15, 1904.

The Prussian Government collects over £76,000 annually as revenue from the amber mines at Palmnicken. From 1803 to 1811, the industry had to receive a subsidy from the Government; now it is self-supporting. In the 20 years from 1883 to 1902, the Palmnicken mines produced 8457 metric tons of amber, the record being established in the last three years. The value of amber used in America in 1903 was \$210,709, making it the second largest consumer in the world.

XVI.—SUGAR, STARCH, Etc.

DENATURED SUGAR (CATTLE FOOD).

N. Nerinx. Bull. Assoc. Chim. Sucr. Dist., 1904, 22, 380—389.

From the official statistics of the consumption of sugar in Belgium denatured for cattle feeding, it appears that the consumption of molasses is stationary, while that of denatured sugar is increasing.—L. J. DE W.

SUGAR INDUSTRY OF CUBA.

Foreign Office Annual Series, No. 3315.

The following table shows the total production and exportation of Cuban sugar during the past three crop

years, as taken from the brokers' report published in Havana:—

Crop.	Quantity.	
	Produced.	Exported.
	Tons.	Tons.
1900-01	635,856	560,570
1901-02	850,181	761,077
1902-03	998,878	879,200
Estimate for 1903-04	1,050,000	..

The difference between the amount produced and that exported represents the local consumption, plus the stock on hand at the end of each year. The above figures represent the results of the crop year commencing on December 1, for which reason they do not coincide exactly as regards the amount exported with those published in the annual returns of imports and exports.

The production of sugar is now as large as in the best year before the insurrection.

XVII.—BREWING, WINES, SPIRITS, Etc.

ALCOHOL INDUSTRY OF ITALY.

Board of Trade J., Dec. 22, 1904.

According to *H. Sole* (Milan) of 2nd December, 22,279,633 litres of alcohol were made in Italy during the financial year 1903-04, and the tax on the distillation thereof received by the State amounted to 31,330,658 lire. In the previous year the output was 17,627,627 litres and the tax 24,259,716 lire.

The development which is taking place in the production of denatured alcohol is satisfactory. Denatured alcohol is exempt from taxation if it is made from the refuse of grapes, &c. ("vinasse"), or from wine, but it pays 10 lire per hectolitre if it is produced from non-vinous matter. During the last year the quantity of denatured or industrial alcohol made from wine or the refuse of the cellars was 258,437 litres, and that of denatured alcohol from other substances was 1,420,547 litres.

Prior to the introduction of the existing law on alcohol the production thereof for industrial purposes was insignificant in Italy, but it is considered that the consumption of denatured alcohol would be far greater than it is at present if industrial firms were to introduce simple and cheap apparatus for lighting and heating purposes.

SPIRIT: PROPOSED TAX ON DENATURED —, IN SWITZERLAND.

Chemist and Druggist, Dec. 24, 1904.

It is reported that the Swiss Government proposes to impose a tax on denatured spirit for trade and industrial purposes. The Soc. pour l'Industrie Chimique à Basle has already lodged a petition with the Federal Council protesting against the abolition of free imports of denatured spirit. The petition points out that the Swiss chemical industry employs over 15,000 workers, and that exports are worth £1,268,000 per annum, the imports being £1,540,000. The severity of German competition is attributed to industrial spirit being free from duty in Germany.

GAUCIAN SPIRIT INDUSTRY IN 1903.

Z. Spiritusind., 1904, 27, 507.

During the year 1903 a strong demand prevailed in the spirit market, and, in consequence of the poor potato harvest, advanced prices resulted. In the distilling season, from September, 1902, to April, 1903, the 750 distilleries in Galicia produced 785,000 hectol., of which 295,000 hl. were refined in the country. The consumption in the province was 230,000 hl.; 125,000 hl. were exported, chiefly to Italy and the Levant. The total production of spirit in Austria was 1,017,000 hl.—J. F. B.

Patent List.

N.B.—In these lists "A" means "Application for Patent," and "C.S." "Complete Specification Accepted."

Where a Complete Specification accompanies an Application, an asterisk suffices. The dates given are (i) in the case of Applications for Patents, the dates of application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which announcements of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

- [A.] 27,063. Pudney. Heating receptacles. Dec. 12.

 „ 28,297 (1903). Shaw. Treatment or preparation of sugar. Dec. 30.
 „ 11,103 (1904). Wheatley. (Int. Spiritus-Ind.) *See under XVII.*

XVII.—BREWING, WINES, SPIRITS, ETC.

- [A.] 27,396. Stead and Palmer. Means and apparatus for collecting carbonic acid gas from fermentation backs, &c., and sterilising same. Dec. 15.
 „ 27,626. Livingstone. Method of desiccating and preserving yeast and apparatus therefor. Dec. 17.
 „ 27,657. Squire, Squire and Squire. *See under XVIII. A.*
 [C.S.] 4294 (1904). Krueger. Malting apparatus. Dec. 30.
 „ 4560 (1904). Leaker. Brewing, distilling and like processes, and apparatus therefor. Dec. 30.
 „ 11,103 (1904). Wheatley (Int. Spiritus-Ind. G. m. b. H.). Method of preparing must for the manufacture of spirits of wine, the feeding of cattle, and the manufacture of dextrose. Dec. 30.
 „ 20,534 (1904). Nathan. Brewing beer. Dec. 21.
 „ 24,994 (1904). Van de Kerckhove and Lebbe. Fermentation and clarification of alcoholic liquids. Dec. 30.

XVIII.—FOODS; SANITATION, WATER PURIFICATION; & DISINFECTANTS.

(A.)—FOODS.

- [A.] 27,266. Aufberg. Process for preparing food products containing iron.* Dec. 14.
 „ 27,390. Williams and Hutchins. Preparation of leguminous proteids. Dec. 15.
 „ 27,391. Williams and Hutchins. Non-alcoholic aerated beverages. Dec. 15.
 „ 27,516. Jung. Method of preserving milk and milk compounds. Dec. 15.
 „ 27,657. Squire, Squire and Squire. Manufacture of yeast for bakers' use. Dec. 19.
 [C.S.] 2065 (1904). Hatmaker. Dry milk and process for obtaining same. Dec. 21.
 „ 11,103 (1904). Wheatley (Int. Spiritus-Ind. G. m. b. H.). *See under XVII.*
 „ 20,292 (1904). Taylor. Cream product. Dec. 21.

(B.)—SANITATION; WATER PURIFICATION.

- [A.] 28,239. Howatson and Boby. Apparatus for mixing and distributing chemicals for purposes of purifying and sterilising water and impure effluents.* Dec. 23.
 [C.S.] 27,968 (1903). Swan. Process and apparatus for purifying air. Dec. 21.
 „ 16,931 (1904). Dorling. Sterilisation of water. Dec. 30.

(C.)—DISINFECTANTS.

- [A.] 26,145A. Hodgkinson. Means for rendering bags, sacks, cloth and other fabrics, and yarns antiseptic. Dec. 16.
 [C.S.] 3669 (1904). Harris. Insecticides. Dec. 21.

XIX.—PAPER, PASTEBOARD, ETC.

- [A.] 27,389. Barker. Blotting paper and the manufacture thereof. Dec. 15.
 „ 28,283. Bonlt (A. Molling und Co., Kommandit. Ges.). Process for preparing picture or like drawing surfaces.* Dec. 23.
 [C.S.] 27,587 (1903). Pfeifer. Process and apparatus for the manufacture of paper stock or pulp. Dec. 30.
 „ 28,611 (1903). Milne. Paper and pulp-making machines. Dec. 21.
 „ 9277 (1903). Woodward. Process for the production of non-inflammable celluloid. Dec. 30.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

- [A.] 28,035. Johnson (Boehringer und Soehne.). Manufacture of camphor from isoborneol.* Dec. 21.
 „ 28,144. Wellcome, Jowett and Barger. Manufacture of pyocatechol derivatives. Dec. 22.
 „ 28,149. Newton (Bayer und Co.). Manufacture of pyrimidine derivatives. Dec. 22.
 [C.S.] 710 (1904). Weichardt. Anti-toxins. Dec. 21.
 „ 7875 (1904). Johnson (R. Koepf und Co.). Manufacture of formates. Dec. 30.
 „ 18,602 (1904). Askenasy and Mugdan. Process for producing acetylene tetrachloride. Dec. 30.
 „ 23,569 (1904). Lauch and Voswinkel. Process for manufacturing condensation products from tannin-like substances and urea by means of formaldehyde. Dec. 21.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

- [A.] 27,141. Dahl. Colour photography. Dec. 13.
 .. 27,267. Krebs. Compositions for use in artificial lighting for photographic purposes.* Dec. 14.
 .. 27,268. Krebs. Compositions for use in artificial lighting especially for photographic purposes.* Dec. 14.
 .. 27,465. Lüttke, Arndt and Löwengard. Flash powder for producing artificial light for photographic and other purposes.* Dec. 16.
 .. 27,466. Lüttke, Arndt and Löwengard. Flash light cartridges for producing artificial light for photographic and other purposes.* Dec. 16.
 .. 27,589. Morgan. Artificial light for photographic purposes. Dec. 17.
 [C.S.] 23,098 (1904). Gärtner. Process of and means for the production of relief photographs or the like. Dec. 30.

XXII.—EXPLOSIVES, MATCHES, Etc.

- [A.] 27,162. Allison. (Muller-Jacobs.) Explosive compound and method of manufacturing same.* Dec. 13.
 .. 27,166. Lheure. Manufacture of explosives.* Dec. 13.
 .. 27,459. Lheure. Explosives. Dec. 16.
 .. 27,460. Lheure. Explosives and priming same. Dec. 16.
 .. 27,706. Mikolajczak. Manufacture of nitro-glycerine. [Ger. Appl., March 19, 1904].* Dec. 19.
 .. 28,256. Ceipek. Manufacture of safety explosives. Dec. 23.
 [C.S.] 4028 (1904). Hargreaves, and Curtis's and Harvey, Ltd. Blasting compounds. Dec. 21.
 .. 6353 (1904). Hargreaves, and Curtis's and Harvey, Ltd. Blasting compounds. Dec. 21.
 .. 24,782 (1904). Duttonhofer. Manufacture of explosives. Dec. 21.

JOURNAL OF THE Society of Chemical Industry.

A RECORD

FOR ALL INTERESTED IN CHEMICAL AND ALLIED MANUFACTURES.

ISSUED TWICE A MONTH.

No. 2.—Vol. XXIV.

JANUARY 31, 1905.

No. 2.—Vol. XXIV.

Subscription of Members 25 - per annum ;
Entrance Fee 21 - ;
Election by the Council.

Price to Non-Members 36 - per annum ;
To Members 25 - per Set of extra or back numbers.
Single copies (Members and Subscribers only).
1882—1901, 2 6 each, 1902 *et seq.*, 1 9 each.

The Society of Chemical Industry.

Past Presidents :

Sir Henry E. Roscoe, B.A., D.C.L., LL.D., Ph.D., F.R.S.	1881—1882.
†Sir Frederick A. Abel, Bart., K.C.B., G.C.V.O., D.C.L., D.Sc., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, LL.D., Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Sir James Dewar, M.A., LL.D., F.R.S.	1887—1888.
Ludwig Mond, Ph.D., F.R.S.	1888—1889.
†Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
†E. Rider Cook	1890—1891.
J. Emerson Reynolds, M.D., F.R.S.	1891—1892.
Sir John Evans, K.C.B., D.C.L., LL.D., Sc.D., F.R.S.	1892—1893.
†E. C. C. Stanford	1893—1894.
T. E. Thorpe, C.B., LL.D., Sc.D., Ph.D., F.R.S.	1894—1895.
Thomas Tyrer	1895—1896.
†Edward Schunck, Ph.D., F.R.S.	1896—1897.
Frauk Clowes, D.Sc.	1897—1898.
George Beilby	1898—1899.
C. F. Chandler, D.Sc., M.D., Ph.D., LL.D.	1899—1900.
Sir Jos. W. Swan, D.Sc., M.A., F.R.S.	1900—1901.
Ivan Levinstein	1901—1903.
Sir W. Ramsay, K.C.B., D.Sc., LL.D., F.R.S.	1903—1904.

† Deceased.

COUNCIL FOR YEAR ENDING JULY 1905.

President : Wm. H. Nichols, M.S., LL.D., D.Sc.

Vice-Presidents :

Prof. P. Phillips Bedson.	Ivan Levinstein.
Dr. Virgil Coblenz.	Max Muspratt.
Dr. Edw. Divers, F.R.S.	T. J. Parker.
Prof. W. R. E. Hodgkinson.	Dr. F. B. Power.
E. Grant Hooper.	Sir Wm. Ramsay, K.C.B., F.R.S.
David Howard.	Thos. Tyrer.

Ordinary Members of Council :

Dr. J. Grossmann.	B. E. R. Newlands.
Oscar Guttman.	Prof. W. J. Pope, F.R.S.
H. Hemingway.	Dr. Boverton Redwood.
Prof. W. R. Lang.	Walter F. Reid.
Dr. J. Lewkowitsch.	Frank Scudder.
N. H. Martin.	Dr. W. S. Squire.

Sectional Chairmen and Secretaries :

Dr. F. J. Smale.	ALFRED BURTON.
Eustace Carey.	LIVERPOOL.
A. Gordon Salamon.	LONDON.
J. Carter Bell.	MANCHESTER.
Dr. J. T. Dunn.	NEWCASTLE.
Dr. Russell W. Moore.	NEW YORK.
J. T. Wood.	NOTTINGHAM.
R. T. Thomson.	SCOTTISH.
Prof. A. Liversidge, F.R.S.	SYDNEY, N.S.W.
Prof. H. R. Procter.	YORKSHIRE.

Honorary Treasurer :

Samuel Hall, East London Soap Works, Bow, E.

Honorary Foreign Secretary :

Dr. Ludwig Mond, F.R.S.

General Secretary : Charles G. Cresswell.

Offices : Palace Chambers, 9, Bridge Street, Westminster, S.W.

Telegraphic Address : 59, Palatable, London.

THE JOURNAL.

Publication Committee :

The President.

Julian L. Baker.	Charles A. Kohn, M.Sc., Ph.D.
G. Beilby.	Ivan Levinstein.
J. Carter Bell.	J. Lewkowitsch, Ph.D.
Joseph Bernays, M.I.C.E.	A. R. Ling.
H. Brunner.	W. Macnab.
Edw. Divers, M.D., D.Sc., F.R.S.	N. H. Martin.
Sir John Evans, K.C.B., F.R.S.	B. E. R. Newlands.
T. Fairley.	John Pattison.
Prof. A. G. Green.	Prof. W. J. Pope, F.R.S.
Samuel Hall.	F. B. Power, Ph.D.
John Heron.	Prof. H. R. Procter.
D. B. Hewitt, M.D.	Sir Wm. Ramsay, K.C.B., F.R.S.
Prof. W. R. E. Hodgkinson,	Boverton Redwood, D.Sc.
Ph.D.	Walter F. Reid.
E. Grant Hooper.	John Spiller.
David Howard.	W. S. Squire, Ph.D.
Julius Hübner.	L. T. Thorne, Ph.D.
Prof. A. K. Huntington.	Thomas Tyrer.
Wm. Kellner, Ph.D.	

Editor :

Watson Smith, 34, Upper Park Road, Haverstock Hill, N.W.

Assisted by the following Staff of Abstractors :

H. Ballantyne II., XII.	A. G. Levy, B.Sc. VIII., IX.

		L. J. de Whalley, B.Sc. XVI.

Canadian Section.

Chairman: F. J. Smale.
Vice-Chairman: W. H. Ellis.
Phos. Macfarlane

Committee:

J. Wats. P.	W. R. Lang.
Jeffrey H. Fairbank	A. McGill
Thos. D. V. S.	W. Lash Miller
G. P. Garfield	Jas. P. Murray
W. L. G. Edwin	Harold Van der Linde
Edgar B. K. Brock	

Hon. Local Secretary: M. J. Taylor, 71, Front Street East, Toronto

Hon. Local Secretary:

Alfred Burton, 42, Front Street West, Toronto

New York Section.

Chairman: Russell W. Moore.
Vice-Chairman: Geo. C. Stone.

Committee:

L. Baekeland.	Wm. McMurtrie.
Chas. F. Chandler.	H. A. Metz.
V. Coblenz.	Wm. H. Nichols.
G. Drobegg.	T. J. Parker.
A. H. Elliott.	F. Schmiewind.
E. G. Love.	C. B. Zabriskie.

Hon. Treasurer: R. C. Woodcock.

Hon. Local Secretary:

H. Schweitzer, 40, Stone Street, New York, U.S.A.

Liverpool Section.

Chairman: Eustace Carey.
Vice-Chairman: Frank Tate

Committee:

F. Lewis Bailey.	Max Muspratt.
G. C. Clayton.	E. L. Peck
J. T. Conroy.	Alt. Smetham.
A. Foden	H. B. Stocks
G. Watson Gray	J. W. Towers.
C. Longuet Higgins	

Hon. Treasurer: W. P. Thompson.

Hon. Local Secretary:

W. R. Hardwick, 13, Batavia Buildings, Hackins Hey, Liverpool.

Nottingham Section.

Chairman: J. T. Wood.
Vice-Chairman: S. F. Burford.

Committee:

L. Archbutt.	J. O'Sullivan.
F. J. R. Carulla.	J. M. C. Paton.
R. M. Caven.	A. L. Stern.
J. Golding.	G. J. Ward.
F. Stanley Kipping.	J. White.
H. B. Mayfield.	

Hon. Treasurer: S. J. Pentecost.

Hon. Local Secretary:

S. R. Trotman, King's Walk Chambers, Parliament Street, Nottingham.

London Section.

Chairman: A. Gordon Salomon.
Vice-Chairman: R. J. Friswell.

Committee:

H. G. Colman.	A. R. Long.
J. N. Comah.	Wm. Pearce.
Bernard Dyer.	Boverton Redwood.
Oscar Guttman.	Walter F. Reid.
J. T. Hewitt	L. T. Thorpe.
D. L. Howard.	Thos. Tyrer.
J. Lewkowitzch.	Clas. Wightman.

Hon. Local Secretary:

Julian L. Baker, 7, Addison Road, Bedford Park, W.

Scottish Section.

Chairman: R. T. Thomson.
Vice-Chairman: J. S. Macarthur.

Committee:

W. S. Curphey.	Jas. Hendriek.
L. Dobbin.	Jas. Hope.
D. B. Dott.	H. Ingle.
Thos. Ewan.	W. G. Johnston.
J. Arnold Flenning.	J. Falcouer King.
W. Frew.	M. A. Parker.
G. H. Gemmell.	T. L. Patterson.
R. Hamilton.	D. J. Playfair.

Hon. Secretary and Treasurer:

Thomas Gray, c/o Gourlay and Deas, 180, Hope Street, Glasgow.

Manchester Section.

Chairman: J. Carter Bell.
Vice-Chairman: F. Seudder.

Committee:

J. Allan.	B. Hart
J. Burger.	W. B. Hart.
R. Clayton.	K. Markel.
W. H. Codeman.	W. J. Pope.
G. J. Fowler.	H. Porter.
J. Grossmann.	W. Thomson.

Hon. Local Secretary:

Julius Hubner, Ash Villa, Chadde Hubner, Cheshire

Sydney, N.S.W., Section.

Chairman: A. Liversidge.

Committee:

W. A. Dixon.	J. A. Schofield.
J. F. Elliott.	R. Greig Smith.
L. Meggitt.	H. G. Smith.
J. Morison.	T. Steel.
A. A. Ramsay.	

Hon. Local Secretary:

T. F. Walton, Colonial Sugar Co., O'Connell Street, Sydney, N.S.W.

Newcastle Section.

Chairman: J. T. Dunn.
Vice-Chairman: W. L. Remondson

Committee:

P. P. Bedson.	W. W. Procter.
H. S. Collins.	Geo. Sison.
Ellwood Holmes.	Harry Smith.
H. Louis	A. Spiller.
N. H. Martin.	J. E. Stead.
John Pattinson.	C. E. Stuart.

Hon. Local Secretary and Treasurer:

F. C. Garrett, Durham College of Science, Newcastle-on-Tyne.

Yorkshire Section.

Chairman: H. R. Procter.
Vice-Chairman: G. W. Slatter.

Committee:

W. Ackroyd.	W. M. Gardner.
C. S. Bedford.	F. W. Richardson.
J. E. Bedford.	A. Smithells.
F. Branson.	Geo. Ward.
B. A. Burrell.	Thorpe Whitaker.
John W. Cobb.	

Hon. Local Secretary and Treasurer:

T. Fairley, 17, East Parade, Leeds.

Official Notices.

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

List of Members Elected.

January 23rd, 1905.

- Atkinson, James P., Department of Health, 55th Street and 6th Avenue, New York City, U.S.A., Chemist.
- Beasley, John K., c/o The Duff Development Co., Ltd., Kelantan, Federated Malay States, Metallurgical Chemist.
- Blyth, Thomas R., Uphall Chemical Works, Hford, Essex, Analytical Chemist.
- Bogardus, Chas. E., 90, Columbia Street, Seattle, Wash., U.S.A., Assayer and Chemist.
- Bond, John, Crowlands, Southport, Engineer.
- Brown, Harold G. S., c/o Messrs. G. H. Ogston and Moore, Strada degli Argentieri 19, Messina, Sicily, Analyst.
- Bryce, Clarence H., c/o Benj. Moore and Co., 244, Water Street, Brooklyn, N.Y., U.S.A., Factory Superintendent.
- Burtenshaw, Wm. H., P.O. Box 814, Detroit, Mich., U.S.A., Secretary and Treasurer, Michigan Carbon Works.
- Cain, Dr. J. C., 28, Pembury Road, Lower Clapton, N.E., and c/o Brooke, Simpson and Spiller, Ltd., Hackney Wick, N.E., Manager and Head Chemist.
- Cheke, T. W., 7, Elm Grove, Stroud Green, London, N., Analytical Chemist.
- Chick, Oliver, 52, High Street, Hornsey, N., Analytical Chemist.
- Conner, Arthur B., 620, Walnut Street, Niagara Falls, N.Y., U.S.A., Chemist.
- Cowles, Horace W., jun., Box 225, Hinsdale, Du Page Co., Ill., U.S.A., Assistant Chemist.
- Crighton, W. H., 33, Ardleigh Road, Southgate Road, London, N., Chemist.
- Dowbiggin, Jas., Pentland Cottage, Lancaster, Chemist.
- Dunlop, Harry, Gragdarroch, Cove, Dumbartonshire, Chemist.
- Durand, Halsey, Department of Health, 55th Street and 6th Avenue, New York City, U.S.A., Assistant Chemist.
- Emery, Delevan, Bradford, Pa., U.S.A., Oil Refiner.
- Epstein, Dr. W., 98, Southhill Park, Hampstead Heath, N.W., Chemist.
- Etheridge, Arthur Thomas, c/o Kynoch, Ltd., Kynochtown, Essex, Chief Chemist.
- Evans, John, 67, Surrey Street, Sheffield, Analytical Chemist.
- Fernberger, Harry M., Acker Process Co., Niagara Falls, N.Y., U.S.A., Chemist.
- Garle, John L., Sanctuary House, Tothill Street, Westminster, Consulting Chemist.
- Gibson, John, Victorian Portland Cement Works, Burnley Street North, Richmond, Vic., Australia, Manager.
- Gibson, W. F., 60, Parrock Street, Gravesend, Kent, Works Chemist.
- Gilliland, Elijah P., 79, Highland Avenue, Salem, Mass., U.S.A., Foreman Tanner.
- Greiner, F. M., Ensley, Ala., U.S.A., Steel Melter.
- Gundlich, Dr. Charles, c/o Therium Chemical Co., Maywood, N.J., U.S.A., Technical Chemist.
- Hall, Archibald A., Armstrong College, Newcastle-on-Tyne, Demonstrator in Chemistry.
- Hanson, H. Norman, Field Head, Brighouse, Yorks, Research Assistant.
- Harper, Dr. Henry W., The University of Texas, 2208, San Antonio Street, Austin, Tex., U.S.A., Professor of Chemistry.
- Hind, H. Lloyd, 55, Stanton Road, Batten on Tere, Analytical Chemist.
- Hobson, Alfred, Duntize Brewery, Imperial Street, Regent Street, Leeds, Spruce Beer Brewer and Manufacturer of British Wines.
- James, O. S., 227, George Street, Toronto, Canada, Analytical Chemist.
- Katzenbach, Welling S., 120, East 34th Street, New York City, U.S.A., Chemist.
- Lee, John C., Mountfort Street, Brookline, Mass., U.S.A., Assistant Engineer, Amer. Telegraph and Telephone Company.
- Liley, Thomas M., 37, Aston Road, Brandleigh, and Whitehall Soap Works, Leeds, Chemist.
- Lomax, Abraham, 30, Taskers Lane, Kearsley, Farnworth, R.S.O., Potters' Chemist.
- Lowe, Houston, The Lowe Brothers Co., Dayton, Ohio, U.S.A., Paint and Varnish Maker.
- Marsh, John, 6, Netherby Terrace, South Stifford, Gray., Essex, Cement Works Chemist.
- Marx, Dr. Max, 81, Shanley Avenue, Newark, N.J., U.S.A., Manufacturing Chemist.
- Merrin, A. C., 44, Bishopsgate Street Without, London, E.C., Assistant Editor and Analyst.
- Merz, Eugene, P.O. Box 216, Newark, N.J., U.S.A., General Superintendent, Heller and Merz Co.
- Milne, Thomas, c/o Gas Light and Coke Co., Ltd., 4, Finchurch Avenue, London, E.C., Chemical Products Salesman.
- Modi, E. M., Opposite Grant Road Station, Sleater Road, Bombay, Manufacturing and Analytical Chemist.
- Moss, William, Moss Chemical Manufacturing Co., 11-15, Carlaw Avenue, Toronto, Canada, Ammonia Manufacturer.
- Needham, G., 54, Queen Elizabeth Street, London, S.E., Druggists' Manager.
- Newall, Joseph, 28, Greenway Road, Runcorn, Cheshire, Chemist.
- Norton, F. A., Brookings, S. Dak., U.S.A., Instructor in Chemistry, South Dakota Agricultural College.
- Ollenbach, D. S., Cordite Factory, Aranyankad, Nilgiris, India, Assistant Surgeon under the Government of India.
- Palethorpe, Percy R., The Tobacco Warehousing and Trading Co., 11th and Magnolia Avenues, Louisville, Ky., U.S.A., Chemist and General Manager.
- Parr, Prof. S. W., University of Illinois, Urbana, Ill., U.S.A., Professor of Applied Chemistry.
- Peuchot, Alf., 129, Crosby Street, New York City, U.S.A., Manufacturer of Chemicals.
- Pickard, Greenleaf W., Amer. Telegraph and Telephone Co., 125, Milk Street, Boston, Mass., U.S.A., Electrical Engineer.
- Priest, George Wesley, Mansfield, Mass., U.S.A., Manufacturer.
- Pyman, Dr. Frank Lee, The Oaks, Hitchin, Herts, Chemist.
- Richardson, L. G., c/o Messrs. Edwd. Ripley and Son, Ltd., Bowling Dye works, Bradford, Yorks, Chemist.
- Rogers, Dr. Allen, 346, Madison Avenue, Flushing, N.Y., U.S.A., Research Chemist.
- Ryan, Prof. F. G. (Journals), c/o Parke, Davis and Co., Anal. Dept., Detroit, Mich., U.S.A., and (subs.) c/o Parke, Davis and Co., 111, Queen Victoria Street, London, E.C., Manufacturing Chemist.
- Sabin, Alvah Horton, P.O. Box 85, Long Island City, N.Y., U.S.A., Varnish Works Chemist.
- Simpson, H., 120, Dennan Street, Radford, Nottingham, Works Chemical Assistant.
- Smith, Hugh Dumford, 8 and 10, The Side, Newcastle-on-Tyne, Analytical Chemist.
- Steiner, Dr. Otto, The Penpoll Tin Smelting Co., Ltd., Bootle, Liverpool, Electro-chemist.
- Strange, Wm. W., jun., Reduction Works, Anaconda Copper Mining Co., Anaconda, Montana, U.S.A., Chemist.
- Tavean, René de Mortemer, 1218, Mt. Royal Avenue, Baltimore, Md., U.S.A., Research Assistant, Johns Hopkins University.

Van Arsdale, G. D., c/o Copper Queen Consolidated Mining Co., 99, John Street, New York City, U.S.A., Chemist.
 Widmann, Eugene A., 866, Park Place, Brooklyn, N.Y., U.S.A., Dyestuff Merchant.
 Wittmack, Dr. Chas. A., 606, West 113th Street, New York City, U.S.A., Chemist.

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps in the verification of addresses, on which the safe delivery of the Journal depends.

Anderson, Dr. W. Carrick: Journals to 7, Scott Street, Garnethill, Glasgow.
 Ashley, Harrison F., 1 o East Liverpool: 233, West 11th Avenue, Columbus, Ohio, U.S.A.
 Bate, Wm.: Journals to "Ledbrooke," Hayle, Cornwall.
 Beckett, G. H., 1 o Stevenson: Hartford, South Beach Road, Ardrossan, Scotland (not New York City, as in January 16th number).
 Bedson, Prof. P. Phillips, 1 o Durham College of Science; Armstrong College, Newcastle-on-Tyne.
 Bowen, W., 1 o Woodend Road; Rockingham, Cecil Road, Erdington, Birmingham.
 Bower, Frank: Journals to Brewery House, Spitalfields, E.
 Bowing, Jno., 1 o Tilbury: 101, North Street, Wandsworth, S.W.
 Carson, Geo. C., 1 o Redding, Cal.; Hotel Broadway, Denver, Colo., U.S.A.
 Collins, J. H., 1 o London: Crinnis, Par Station, Cornwall.
 Cunliffe, A. J., 1 o Whittle-le-Woods; Claytonfield, Clayton-le-Woods, Chorley, Lancs.
 Davis, Geo. E., 1 o Knutsford, Cheshire: 265, Strand, London, W.C.
 Dodds, Roger: Journals to Bigot's Hall, Dunmow, Essex.
 Eastwood, Edw.: all communications to 7, Bolton Road, Port Sunlight, Cheshire.
 Evershed, F., 1 o Atlas Works; c/o Clarke, Nickolls and Coombs, Hackney Wick, N.E., Chemist.

MR. EUSTACE CAREY IN THE CHAIR.

STUDIES ON THE CLAUS KILN REACTION.

PART III.

INFLUENCE OF VARIOUS CONTACT SUBSTANCES ON THE INTERACTION OF STEAM AND HYDROCYANIC ACID

(Both in Presence and in Absence of Sulphuretted Hydrogen and Air).

BY R. FORBES CARPENTER AND S. E. LINDER, B.Sc.

We present below the continuation of our work on the above subject, the first stages of which were described in our previous paper (*Journal*, 1904, pp. 584-6). As mentioned in the discussion following that paper, we saw reason to modify the apparatus then used in order that not only might the percentage conversion into ammonia be measured, but an estimation be also made of the gaseous reaction products passing from the ammonia catch.

The volume of the experimental Claus kiln used in the earlier experiments was large compared to that of the reacting mixture, and, in addition, from the presence of joints in the apparatus, diffusion inwards of products of combustion from the heating jacket was more or less liable to occur.

In the present research an attempt is made to follow more closely the nature of the reactions that occur by estimating all the reaction products, and, in addition, to accumulate the data necessary to decide the various factors controlling a high yield of ammonia. For this end the iron kiln then in use was replaced by a combustion tube of glass, the contact material was presented to the reacting mixture in a long column of small sectional area, and the acid receivers and water seals were reduced in size to facilitate collection of the gaseous products. The following is a brief description of the arrangement finally adopted:—

By use of a gasholder of special construction a known volume of gas of uniform composition and at any desired rate and pressure could be delivered to a generating flask through a small Drechsel's bottle, serving as water seal. In the first series of experiments carbon dioxide alone was used, in the later carbon dioxide, sulphuretted hydrogen and air. The generating flask consisted of a 300 c.c. distilling flask containing excess of dilute sulphuric acid (1 of acid to 10 of water) maintained at a temperature somewhat above 100° C. by a bath of glycerine and water. The desired proportion of hydrocyanic acid was added to the gaseous current by admitting a concentrated solution of potassium cyanide (25 c.c., containing 3 grams potassium cyanide) of determined strength through a small bore tube coupled to a pipette. An approximate estimate of the weight of steam present in the gaseous mixture leaving the flask was deduced from the weights of reacting solutions before and after passage of the gas, due allowance being made for the weight of hydrocyanic acid liberated by the acid, and for the weight of steam resulting from oxidation of sulphuretted hydrogen.

The volume and composition of the reacting mixture and its rate of flow varied somewhat throughout the series, as exact adjustment of the working of the various parts of the apparatus was not easy to ensure, but in general the volume of gas entering the generator from the gasholder was 2½ to 3 litres, and that of the hydrocyanic acid resulting from interaction of potassium cyanide and acid about 900 c.c., yielding a reacting mixture containing 20 to 30 volumes of hydrocyanic acid per 100 volumes of permanent gas. The weight of steam present in the reaction was always maintained in large excess of that theoretically required for decomposition of the hydro-

cyanic acid—from 5 to 15 molecules H₂O per molecule HCN. Each experiment lasted from 80 to 90 minutes, the last 20 of which were occupied in driving the reaction products forward to the terminal receiver after reaction in the generating flask had completed itself. Further details are given in the paper and in the appendix.

Contact Tube and Furnace.—The contact material was in each case reduced to fragments about the size of a pea, carefully sieved to remove dust and dried by heating. In the case of broken brick and oxide of iron pre-ignition was carried to a red heat to ensure expulsion of water; with Weldon mud gentle heat was used to avoid risk of loss of oxygen. The length of the contact column throughout was 22 inches, with a diameter of 1½ inch; it was contained in a combustion tube of Jena glass 29 inches long, slightly inclined downwards from the inlet end to minimise creeping of the gases along the upper side of the tube. Plugs of asbestos fibre were placed at each end to retain the column in position and minimise risk of fracture from direct contact of condensed water with the hot glass. The asbestos plug at the exit end served the further purpose of a filter, and its examination for oxidised sulphur compounds of ammonia, *e.g.*, sulphate, thiosulphate, pentathionate, &c., in the later series of experiments, when sulphuretted hydrogen and air were present in the reacting mixture, affords data of considerable interest (see p. 68).

The combustion tube was shielded from direct contact with the furnace gases by an enclosing jacket of ½ inch steel, and from the jacket itself by a thin plate of earthenware. The jacket was heated by an Erlenmeyer furnace, by which it was readily maintained at any desired temperature within a range from 150° C. to 700° C. Temperatures throughout were determined by the Siemens copper bolt calorimeter, checked at lower temperatures by direct comparison with a mercurial thermometer. The copper bolt was placed in a small platinum crucible supported in a short iron collar brazed to the upper side of the jacket, the crucible bottom projecting through a hole in the jacket to a point just above the combustion tube within, the whole being enclosed within the roof of furnace tiles above. Special precautions were taken to guard against loss of heat by radiation from the bolt when the covering tile was removed for a temperature determination. The figures so obtained have no absolute value, as the temperature attained by the bolt would be neither that of the iron jacket itself nor of the contact material it enclosed. Attempts to ascertain the exact temperature of the latter were made by inserting a mercurial thermometer into the contact material, but proved unsuccessful as the mercury column parted. In one experiment, however, a thermometer reading was obtained of the iron jacket below the combustion tube. The result showed that the difference between the upper and lower sides of the jacket is not great. Thus:—

Upper side by thermometer ..	423° F.
.. by Siemens Calorimeter ..	417° F.
Under side by thermometer ..	487° F.

Acid Catch.—In the earlier experiments on broken brick (p. 64) a 500 c.c. retort was used; this was replaced in the later experiments by one of 250 c.c., the smaller capacity of the latter being better adapted for work involving the collection and analysis of gaseous products. A sufficient volume (50 to 70 c.c.) of half-normal acid was used in the catch to fix and retain the ammonium carbonate entering, final traces being absorbed by an acid scrubbing tube on the exit. The residual gases, freed by this means from steam and ammonia, passed through a water seal to a large stoneware aspirator containing oil-covered water. Suitable connections enabled an average sample of the residual gas to be withdrawn on its way to the aspirator at any period of the run, by means of a cylinder filled with mercury or oil-covered water.

Methods of Analysis.

The analysis of the acid retort catch liquors and contents of asbestos filter is considered later (p. 64). Analysis of the inlet and exit gases was made with a Stead's gas apparatus, supplemented by Bunte burette. Carbon monoxide and hydrogen were determined by

explosion with excess of air, followed by the violent elastic soda explosion, the solution being then an occasional ebullition, where the mixture is allowed to explode, and the negligible traces of carbon monoxide being the only signs of the explosion. Hydrocyanic acid is added for in the next stage, shaking with sulphuric acid and distilling the solution of N_2O and cyanate.

Methods of Calculation.

The results of the various reactions involving CO, HCN are calculated from the volume and composition of the residual gases, due to a low percentage of nitrogen present in the reacting mixture. No direct estimation of the CO_2 proved possible, owing to the solubility of this gas in water used to the separation of the carbonate at atmospheric pressure of the reaction, and during certain stages. The limitations imposed by having to operate with large volumes of gas and the difficulty of excluding adventitious air from the apparatus before the experiment commenced, and of completely displacing the reaction product at its close, render it necessary to regard the gas analysis figures with some reserve, but we consider, nevertheless, that they are of valuable indication of the nature of the reactions that occur, especially the figures for nitrogen. Three examples may be given here to illustrate the extent to which the latter varies with altered conditions of working.

1. Brick Contact.

Low yield of Ammonia = 1.2 per cent. of NH_3 as HCN taken.
Undecomposed hydrocyanic acid,
by difference = 95.8 (much HCN in catch).

RESIDUAL GAS—

Calculated.	$\text{CO}_2 = 97.8$	Found.	$= 97.8$
	$\text{O} = .9$		$= .9$
	$\text{N} = 1.3$		$= 1.5$

2. Oxide of Iron Contact.—(See Appendix, pp. 68 and 69 for calculation.)

High yield of Ammonia = 85.3 per cent.
Decomposed to free nitrogen,
by difference = 14.7 (no HCN in catch).

RESIDUAL GAS—

Calculated.	$\text{CO}_2 = 93.1$	Found.	$= 93.2$
	$\text{O} \text{ acc.} = 4.3$		$= 4.3$
	$\text{N} = 2.6$		$= 2.5$

3. Oxide of Iron Contact.

Low yield of Ammonia = 51.5 per cent.
Decomposed to free nitrogen,
by difference = 48.5 (no HCN in catch).

RESIDUAL GAS—

Calculated.	$\text{CO}_2 = 92.6$	Found.	$= 92.8$
	$\text{O} \text{ acc.} = .3$		$= .3$
	$\text{N} = 7.1$		$= 6.9$

Experimental Results.

The research naturally divided itself into an inquiry under two heads:—

(A.) INTERACTION OF STEAM AND HYDROCYANIC ACID IN ABSENCE OF SULPHURETTED HYDROGEN AND AIR.

(B.) DITTO IN PRESENCE OF THOSE BODIES.

Section A formed a necessary preliminary to B.

(A.) Sulphuretted Hydrogen and Air Absent.

Three contact materials were tried—broken brick, oxide of iron, and Weidon mud. Each of these was reduced to fragments of approximately the same size, and presented to the gas under similar conditions (see ante, p. 63). It should, however, be pointed out that the experiments with broken brick preceded the others, and were subject to minor irregularities of procedure and defects of apparatus that were eliminated in the later experiments, and whose removal facilitated collection of the gaseous reaction products. These remarks do not apply to the collection and estimation of ammonia, which is regarded as accurate throughout.

Before discussing the results in detail, attention is directed to some of the more important reactions indicated by theory as likely to occur within the range of conditions observed:—

Kramers (quoting Naumann and Pistor) states that no reaction occurs between steam and carbon monoxide between 530°C . and 585°C ., but begins between 602°C . and 634°C . (*vide Journal of Gas Lighting*, May, 1902, p. 1417).

We shall show, however, in the present work that reactions (1) and (2) occur simultaneously at equal or varying rates, yielding carbon dioxide and free hydrogen at a much lower temperature than this. Thus, say,

These reactions require the presence of oxygen in the contact material, and cannot, therefore, occur with a brick contact in absence of air.

As regards the velocity of reaction (ii) at various temperatures with oxide of iron, interesting results were published (*Journal*, 1900, p. 28) by Messrs. Carrick Anderson and George Lean. The conclusion was there reached that the action of soft brown haematite ore upon ammonia "begins at temperatures between 140°C . and 150°C ., and "that the physical condition of the peroxide as it exists in its various natural and artificial forms, materially influences its activity in the oxidation process." The restraining influence of steam upon the reaction was not investigated. We have set out some of the results obtained by the authors in graphical form on p. 69, for comparison with our own.

(5) Reactions yielding free nitrogen by dissociation.

Formic acid has not been identified by us with certainty among the products of reaction in any experiment.

(7) Reactions of carbon monoxide and hydrogen with oxide of iron and manganese dioxide.

1. Carbon monoxide.—Cleveland iron stone, according to Lowthian Bell "Principles of the Manufacture of Iron and Steel," p. 183, begins to act appreciably on the gas only at temperatures over 200°C . (*vide also Watts's Dict.*, Vol. III., p. 62). Manganese dioxide begins to oxidise CO about 87°C . (*Ibid.*, p. 183).

2. Hydrogen.—Oxidation commences with Cleveland ore at, or about, the same temperature as with carbon monoxide according to Lowthian Bell (also see Watts's, Vol. III., p. 62). Manganese dioxide commences to oxidise H about 190°C . (*Ibid.*, p. 183).

We now proceed to discuss the results given in Table I and graphically on p. 68. They are arranged in order of temperature throughout, this being the most important of the controlling factors for any given contact material:—

Broken Brick.

Appearance as charged dull red; as withdrawn, black. Volumes of reacting mixture (excluding steam) varied from 3580 c.c. to 4495 c.c. measured at 0°C ., 760 m.m.

Duration of experiments from 42 to 106 minutes. The gas analyses are approximate only except in expt. 6, the last of the series in point of time, when apparatus and procedure was identical with that in the case of oxide of iron and Weidon mud contacts.

The conclusions drawn are as follows:—

1. That within a range of temperature from 465° —

19.	350	660	26.4	8.0	.60	100	nil	nil	45	0.4	nil	90	No crystals.

NOTE.—Figures for "HCN undecomposed." These are lower than the correct figure, owing to some loss of hydrocyanic acid on transfer of acid catch liquor from retort catch to stoppered flask for analysis. The error is proportional to the amount of hydrocyanic acid undecomposed.

Figures for "Loss as N." These are subject to errors due to leakage of air into the apparatus in addition to the ordinary errors of analysis discussed on pp. 63-4.

Figures for "NH₃ recovered." These are in every case regarded as correct. They are rounded off to the nearest integer.

625° C. the amount of hydrocyanic acid converted into ammonia approximates to 80 per cent. when rates of flow are equal.

2. That results are characterised by escape of hydrocyanic acid undecomposed, the amount of this body showing marked increase with increased rate of flow.

3. That carbon monoxide and hydrogen are constant products of the reaction, the latter being in marked excess.

That decomposition to free nitrogen is not very pronounced even at the highest observed temperature, 625° C.

The results clearly indicate that reactions (1) and (2) viz. :—

are both operative from 465° to 625° C.

Oxide of Iron.

Physical condition.—Sample of oxide used in gas works Claus kiln previously ignited to expel water.

Appearance when charged, ochreous; as withdrawn, dull brick red.

Volumes of reacting mixture, 3.500 c.c. throughout, at 0° C. 760 mm.

Duration of experiments, 87 to 92 minutes.

he statement, the production of oxidised sulphur derivatives of ammonia is considered later (p. 68).

Broken brick.

Condition.—As withdrawn from use in (A) above.

Volumes of reacting mixture (excluding steam) varied from 3670 to 4165 c.c., 0° C., 760 m.m.

Duration of experiments, 90 to 93 minutes.

The conclusions drawn are as follows:—

1. That the presence of sulphuretted hydrogen and air (in moderate excess) favours a high yield of ammonia, without sensibly modifying the character of the products.

2. That the proportion of air favourable to maximum yield is 3·2 air to 1 H₂S.

3. That results are characterised by absence of nitrogen and undecomposed hydrocyanic acid, and by presence of both carbon monoxide and hydrogen when the proportion of air does not exceed 3·2 : 1 H₂S. With a much higher proportion of air (6·0 : 1 H₂S) free nitrogen, ammonia, carbon dioxide and water are the sole products.

Oxide of iron (sulphided).

Condition.—Sample used was that withdrawn after use in the small laboratory kiln for Claus kiln experiments. See Alkali Report 1899, pp. 181—184. For analysis before and after use in the present series, see Table 4.

Appearance as charged, dull red and grey; as withdrawn, black.

Volumes of reacting mixture varied from 3270 c.c. to 3615 c.c., 0° C., 760 m.m.

Duration of experiments, 86 to 90 minutes.

The following conclusions are drawn:—

1. That the presence of sulphuretted hydrogen and air favours a high yield of ammonia.

2. That results are characterised by absence of undecomposed hydrocyanic acid, and of carbon monoxide and hydrogen.

Weldon Mud (sulphided).

Condition.—Sample used was that withdrawn from the laboratory kiln in 1899, and similar to that used in the Claus reaction tube experiments. (Journal, 1903, p. 460, where the full analysis is given, see also Table 5.)

Appearance as charged, light brown; as withdrawn, ditto.

Volumes of reacting mixture about 3450 c.c., 0° C., 760 m.m. throughout.

Duration of experiments from 86 to 92 minutes.

The following conclusions are drawn:

1. That the presence of sulphuretted hydrogen and air favours a high yield of ammonia, and greatly modifies the nature of the products.

2. That the proportion of air favourable to the maximum yield of ammonia is 2·7 : 1 H₂S, with a temperature of 380° C.

3. That results are characterised by presence of carbon monoxide and hydrogen, and by absence of nitrogen over a range of temperature from 220° C. to 380° C.

Distribution of Recovered Ammonia.

The presence of ammonium sulphate in the sulphur recovered from Claus kilns in gas liquor works, and its relation to the nitrogen entering with the saturator gases in the form of hydrocyanic acid was fully discussed in our previous paper. We then stated (Journal, 1904, p. 586)—

“Whatever its previous history, however, ammonia is undoubtedly present in the exit kiln gases, mainly in combination with sulphuric acid as ammonium sulphate, but in lesser degree also with sulphurous acid as ammonium sulphite; * the latter body would, of course, rapidly suffer oxidation to sulphate when the recovered product is exposed to the air on opening the chambers.”

The question was regarded as one of importance, both practical and theoretical, and attention was therefore specially directed in the present research to the estimation of the various oxidised sulphur compounds of ammonia present in the residual gases resulting from interaction of steam and hydrocyanic acid in presence of sulphuretted hydrogen under conditions approximating to those existing in the Claus kiln itself. For this end the residual gases from the contact material were made to pass through a layer of asbestos fibre before leaving the combustion tube for the acid catch, with a view of filtering out any solid bodies that might be induced to separate by contact with a porous material at a comparatively low temperature (100° to 200° C.) before reaching the acid catch, where such products would be subject, not only to large dilution, but also to decomposition by secondary reaction with the half-normal acid present to retain ammonia. The asbestos fibre was extracted with cold water at the end of each experiment, and the filtered extract submitted to separate examination. The quantitative results are fully set out in tabular form in Table 3 with the analyses

* The iodine-reducing properties of the neutral salt, separating in the sampling tube on this occasion, was attributed to the presence of ammonium sulphite; it is now believed that it should have been properly ascribed to ammonium thiosulphate.

of the corresponding catch liquors. Ammonia as sulphate and thiosulphate was determined by Richardson and Aykroyd's joint iodine and acidimetric method; a united figure for ammonia as pentathionate and bisulphate was arrived at by difference, the presence of these bodies being identified qualitatively by ammonium molybdate, nitrate and barium chloride respectively. Similar methods were employed for the analysis of the residual catch liquors.

We regard the analyses of the asbestos fibre extracts as affording undoubted evidence of the presence of oxidised ammonium sulphur compounds as direct products of the combustion tube reaction.

On the other hand, the thiosulphate and sulphate found in the acid catch liquors are undoubtedly derived in some measure from secondary reactions, and little or no significance can be attached to these figures. Thus, for ammonia as carbonate and sulphate are less open to objection, and are regarded as approximately correct. We summarise the conclusions briefly as follows:

1. *Weldon Mud* (sulphated).

Temperature low, not exceeding 380° C.

Results characterised by presence of small traces of oxidised sulphur compounds in the asbestos filter; and by absence of sulphate in the catch, the bulk of the ammonia appearing as carbonate.

2. *Oxide of Iron* (sulphated).

Temperature high 480° to 520° C.

No conclusions as to the yield of ammonium sulphate can be drawn from the results obtained in experiments Nos. 22 and 23, as the contact material on charging contained a considerable proportion of ferric and ferrous sulphates, bodies which yield sulphur trioxide on ignition; these bodies were absent when the material was withdrawn for analysis at the end of experiment No. 24, the last of this series. Confining attention to No. 24, we see that results are characterised by the presence of oxidised sulphur compounds of ammonia in the asbestos filter, and by the absence of sulphate in the catch.

3. *Broken Brick*.

Temperature high, 565° to 580° C.

Results are characterised by absence of pentathionate, sulphate, and thiosulphate in both asbestos filter and acid catch; and by the large proportion of ammonium carbonate.

For comparative purposes, we have presented in graphical form below some of the more important features of Tables 1 and 2. In Fig. 1 the yields of ammonia per cent. of the maximum attainable by theory are represented as ordinates with corresponding temperatures as abscissae, each observation being denoted by a small circle. The circles are connected by lines, thick black lines indicating results with Weldon mud, thin lines results with oxide of iron, and dotted lines those with broken brick. The character of the reaction products is indicated by the usual symbols placed beside the circle to which they correspond, thus, " $\text{CO}, \text{H}, \text{HCy}$ " denotes that carbon monoxide, hydrogen, and undecomposed hydrocyanic acid are present in the residual gases, while " N " denotes the absence of those bodies and the presence of free nitrogen. In Fig. 2 the amounts of ammonia (or hydrocyanic acid) decomposed to free nitrogen per cent. of total hydrocyanic acid taken are represented as ordinates with the corresponding temperatures as abscissae. The lines and lettering for the same materials are as in Fig. 1. In some cases, results found in the tables have had to be excluded, owing to the rates of flow being abnormal; in others, results are averaged where temperatures and rates of flow approximate. In addition, we have given, in graphical form on the extreme left of Fig. 2, the results obtained by Messrs. Carrick Anderson and George Lean in their experiments on the oxidation of ammonia (in presence of dry nitrogen gas) by haematite ore. (Journal, 1900, p. 28.)

APPENDIX.

Example.—TABLE I. No. 13.

Conversion=85.3 per cent.; Temperature=355°C (=670°F);

HCy absent in catch.

Volume of iron oxide = 216.5 c.c.; Time 90 minutes.

Volume of permanent gas entering decomposer from gas holder = 2,640 c.c. 0°C., 760 m.m.

YIELD OF AMMONIA AND CHARACTER OF PRODUCTS.

FIG. 1.

FREE NITROGEN PRODUCED BY DECOMPOSITION OF AMMONIA (or HYDROCYANIC ACID)

(Steam and Carbon dioxide present)

FIG. 2.

Composition of ditto,
per 100 volumes—

$\text{CO}_2 = 98.4$ and	$2,640 \times .984 = 2,598 \text{ c.c.}$
$\text{O} = .3$	$2,640 \times .003 = 8 \text{ ..}$
$\text{N} = 1.3$	$2,640 \times .013 = 34 \text{ ..}$
	<u>2,640 ..</u>

Reacting Mixture.

1. Permanent gases 0°C , 760 m.m.

CO_2 from gas holder = 2,598.	Whence,	
Add CO_2 from carbonate	per 100 volumes—	
in KCy = 57 = 2,655 c.c.	$\text{CO}_2 = 75.2$	
O from gas holder = 8 ..	$\text{O} = .2$	
N from gas holder = 34 ..	$\text{N} = .9$	
HCN calculated from KCy = 837 ..	$\text{HCN} = 23.7$	
Total = 3,534 ..	100.0	

2. Aqueous vapour 0°C , 760 m.m.

H_2O from gas holder = 70.	Whence rate of	
from decomposer = $8.7 \times 1,000$	flow—	
	c.c. per min.	
	per 1 c.c. packing	
= $\frac{805}{90 \times 216.5} = 14,411$		
Total = 14,411 ..		

Residual Gas.

1. Found in aspirator. Volume = 3,510 c.c. 0°C , 760 m.m.
Composition per 100 volumes
 $\text{CO}_2 = 93.2$ and $3,510 \times .932 = 3,271 \text{ c.c.}$ per 837 volumes HCN entering.

$\text{CO} = 3.7$	$3,510 \times .037 = 130 \text{ ..}$
$\text{O} = .2$	$3,510 \times .002 = 7 \text{ ..}$
$\text{H} = .4$	$3,510 \times .004 = 14 \text{ ..}$
$\text{N} = 2.5$	$3,510 \times .025 = 88 \text{ ..}$
<u>100.0</u>	<u>3,510 ..</u>

Whence $\text{CO} = 15.5$ per 100 volumes, HCN.

$\text{H} = 1.7$..
 $\text{N} = 6.5$..
(Deducting 34 volumes N entering).

2. Calculated from efficiency—

We have, per 100 parts of HCN entering—
Oxidised to ammonia by steam = 85.3 yielding as first products—
 $\text{NH}_3 = 85.3 \text{ vols.}$
 $\text{CO} = 85.3 \text{ ..}$
(= 85.3 CO_2).

Escapes undecomposed nil
Decomposed to nitrogen (by
diff.) 14.7 yielding as products—
 $\text{CO}_2 = 14.7$
 $\text{N} = 7.3$

Whence, the residual gas per 837 c.c. HCN entering should contain, if the CO be fully oxidised—

CO_2 entering contact material = 2,655 c.c. 0°C 760 m.m.
Produced by oxidation of CO

= $85.3 \times 8.37 = 714 \text{ ..}$
Produced by oxidation of
 $\text{HCN} = 14.7 \times 8.37 = 123 \text{ ..} = 3,492 \text{ c.c.}$

N entering contact material = 34
Produced by oxidation of
 $\text{HCN} = 7.3 \times 8.37 = 61 \text{ ..} = 93$
Total = 3,587 c.c.

Whence, per 100 volumes $\text{CO}_2 = 97.4$
 $\text{N} = 2.6$
100.0

Now analysis indicates (see aspirator gas above) that the carbon dioxide and nitrogen are associated with .6 per cent. of oxygen and hydrogen, and that 3.7 per cent. of CO is unoxidised. Correcting for this, we have—

Total volume calculated = 3,587 = 3,610 c.c. 0°C 760 m.m.

Composition per 100 volumes, calculated—
 $\text{CO}_2 = .994 \times 97.4 \text{ less } 3.7 \text{ } \text{CO} = 93.1$
 $\text{CO} = 3.7$
 $\text{O} = .2$ associated = 4.3
 $\text{H} = .4$
 $\text{N} = 2.6$
100.0

TABLE IV.

Analysis of Oxide of Iron Contact before and after Interaction with Hydrocyanic Acid and Steam.

	Oxide of Iron (Air and H ₂ S Absent).		Sulphided Oxide of Iron (Air and H ₂ S Present).

TABLE V.

Analysis of Sulphided Weldon Mud before and after interaction with HCN and steam (air and H₂S present).

	Before.	After.
Manganous sulphate	2.32	—
Calcium sulphate	21.28	—
Magnesium sulphate	0.30	—
Alkalis, as sulphate	3.95	—
Manganese monoxide, MnO	21.69	4.3
dioxide, MnO ₂	11.91	—
sulphide, MnS	absent	—
Calcium oxide (CaO)	0.62	—
Alumina and ferric oxide	traces	—
Sulphur, free (by carbon bisulphide)	21.26	6.0
Silica, &c.	0.81	—

NOTE.—On heating the sulphided mud in carbon dioxide, sulphur dioxide was freely evolved, indicating interaction between the free sulphur and manganese dioxide. This rapid evolution of SO₂ ceased when experiment No. 26, Table II (the first of this series), was half completed. It was not met with in the two following experiments, Nos. 25, 27, when traces only of SO₂ were found in the residual gases.

DISCUSSION.

Mr. COLEMAN inquired whether Mr. Carpenter considered that the protecting effect of the diluting gases was due to the proportion of the gases present or to their specific nature—whether any kind of gas would have a protecting effect.

Mr. MAX MUEPRATT said that the influence which sulphuretted hydrogen seemed to have upon the reactions described by Mr. Carpenter was very striking. Had Mr. Carpenter made any experiments upon the condition of the surface of the contact material after the experiments in which sulphuretted hydrogen was used? Had the sulphuretted hydrogen actually formed a sulphide coating upon the contact material, so that approximately neutral results were obtained as with brick, or did the gas, as such, in some way modify the reaction?

The CHAIRMAN asked what Mr. Carpenter thought ought to be done in practice to increase the yield of the valuable products that could be obtained, and which exist in those gases, or whether he intended to leave it to the practical men to draw their lesson from the experiments which he had made and reported? He noticed that some of the experiments at least were conducted with pure materials and in glass tubes. Many years ago the late Dr. Hurter, in the course of some experiments on the well-known Deacon chlorine process, found that in the laboratory, working with a glass tube and with materials im-

pregnated with a salt of copper, one could pass hydrochloric acid and air through the tube at the requisite temperature, and get unlimited quantities of chlorine, without damaging the copper in the slightest degree. They therefore then jumped to the conclusion that all that was necessary was to build a large piece of apparatus and get a similar result in the works to that which they had obtained in the laboratory, but, unfortunately, such was not the case. Various impurities were present with the hydrochloric acid, such as arsenic and sulphuric acid, and also the impurities resulting from the furnaces themselves; thus it came to pass that, instead of obtaining an unlimited quantity of chlorine from a given amount of the copper salt, they obtained a limited amount, and it resulted, as was well known, in the necessity for small but continuous replacements of the contact material for the carrying out of the process. Had Mr. Carpenter any idea whether the practical results on the large scale would be different from the results that he had obtained in the laboratory? He had been very pleased indeed to hear of the success of the copper calorimeter. Evidently it was very accurate when carefully managed, and he believed that it was about the best calorimeter which could be used for high temperatures, and he thought Mr. Carpenter agreed with him. Of course, some other material, such as a platinum bolt, which was equally good from a practical point of view could be used. In the Dean process they usually used iron bolts, which they thought were quite near enough.

Mr. CARPENTER in reply, said that he certainly considered that the protecting effect of the diluting gases in the second series of experiments was due to their specific nature, because in the first series of experiments they had practically the same volume of permanent gas accompanying the hydrocyanic acid, viz., carbonic acid from the cylinder, and the only other neutral gases in addition to carbonic acid were small quantities of oxygen and nitrogen. As compared with the small Claus kiln of the last paper they got their carbonic acid generally on passing through that apparatus within 2.5 to 3 per cent. of that entering. This exit gas contained about 95 per cent. CO₂, as against 98 going in. In the present series, inlet and outlet tests gave practically identical figure. They had done some experiments at different rates in order to see the effect of increasing speed on the yield. Such experiments were especially made for the purpose of seeing how hard the pressure could be driven without decreasing the yield, but as a rule they tried to run through the same quantity in the same time, as to maintain speed as a constant in studying effects of variations of temperature. In answer to Mr. Muepratt, the oxide of iron contact material was analysed in the first

ries of experiments as regards certain substances that they looked for, and also the sulphided material, before and after use. Before use the oxide was such as was used in the Claus kiln, and there was no ferrie sulphate, the same was the case after use; there was no ferrie sulphate, and only a trace of calcium sulphate; the ferrie oxide was estimated before and after, and it had maintained its character throughout. In the sulphided material, as he had explained in the paper, the previous experiments with that material had been conducted at low temperatures, so that some ferrous and ferrie sulphate were present in the material; these had nearly disappeared in the course of the early present experiments, in the sulphided Weldon mud there was no manganese sulphide present before use, but they found 4.3 per cent. after use. In the paper they described a certain amount of superficial darkening of the broken brick material, which they attributed to the separation of the carbon from some decomposition of hydrocyanic acid. Mr. Carey had asked him a difficult question as to the practical considerations that arose out of the work. He looked upon it rather as a warning to technologists than as suggestions to be followed, because the hydrocyanic acid was so much more valuable than ammonia that all the aims of technologists had been to produce hydrocyanic acid from ammonia rather than ammonia from hydrocyanic acid. This decomposition of hydrocyanic acid was found to occur in the manufacture of cyanide in Germany from the "schlempe," where they got considerable quantities of ammonia as well as hydrocyanic acid; the operations there being conducted at a red heat in brick retorts, and the products passed through highly heated pigeon-hole brick work, so that if they got a yield of ammonia accompanied by nitrogen it was not to be wondered at. Then Mr. Carey had asked a question as regarded the practical suggestions that seemed to arise from the research that had been conducted with a view to the examination of the products from the Claus kilns used in gas works. At the April meeting, when he previously dealt with the subject, a member had indicated he would choose a contact material that would destroy the ammonia, and asked had such experiments been made? The work of the present paper then sketched out the answer, and Mr. H. Morris's remark was one natural practical suggestion that would occur to a sulphuric acid manufacturer using such sulphur. He thought the suggestion would occur to the practical man as he read the paper that it indicated more what to avoid than directly how to obtain what he wanted. Then, as regarded the materials used, the potassium cyanide did contain small quantities of some other salts, chiefly potassium carbonate. In their gas analyses they had to allow for a certain amount of carbonic acid from this source—it was a very small amount. The analyses of the contact materials used were given in the paper. They confined their research purely and strictly to the hydrocyanic acid, not complicating it with any other product except those which accompanied it on a large scale—the sulphuretted hydrogen and carbonic acid in gas works practice. Mr. Clayton had been kind enough to make a suggestion at the last meeting as to whether the methods of analysis of Walther Feld, who had given some extremely useful methods of analysing crude cyanide compounds, had been found satisfactory in such work as Mr. Linder and himself had described in their previous paper. Feld's process for estimation of hydrocyanic acid in presence of sulphides was a simplification of the process that Mr. Linder had independently devised. On the addition of lead nitrate to the cyanide before distillation the solution did become acid by hydrolysis, so that there was no necessity to add an acid like tartaric. He might say that the presence of other than traces of cyanide in gas liquors was a decidedly unusual thing; there were so many other bodies waiting to combine with ammonium cyanide in its passage from the retort to the cooling and scrubbing apparatus that to find it in notable amount in a gas liquor was not in their experience a common thing. He had not been prepared for the almost complete accuracy in estimations by Feld's methods, which they found from various materials used. He hoped some day to hear a paper connected with the cyanide industry on the point under notice.

London Section.

Meeting held at Burlington House, M. J. J.,
January 9th, 1905.

MR. A. GORDON SALAMON IN THE CHAIR.

SOME CHEMICAL ASPECTS OF THE ST. LOUIS EXHIBITION.

BY WALTER F. REID, F.L.C., F.C.S.

The Great Exhibition at St. Louis which has recently closed, contained so much that was novel and suggestive to the chemist that a description of some of the more important points may be of interest. The task of selection is not an easy one, for many of the numerous exhibits were sprinkled over the whole of the exhibition, rendering the work of personal inspection difficult and lengthy. For much valuable assistance in connection with the exhibits I am indebted to my colleague on the International Jury, Mr. H. J. Helm, I.S.O., whose wide experience of chemical products contributed materially to a full appreciation of the merits of our exhibits by our colleagues on the Jury. Mr. C. T. Tyrer rendered valuable assistance in the arrangement of the exhibits, a matter which is too often neglected by British exhibitors who have a tendency to rely solely on the quality of the goods themselves. The British Chemical Section was in charge of Mr. H. Wernicke who possessed the qualification of being an excellent linguist. Particulars about the general arrangement of the exhibition will be found in the *Journal of the Society of Arts*, Dec. 9th, 1904.

There can be no question that the Low Temperature Research Plant of the British Royal Commission was the most important exhibit in group 23. It was a happy thought of the Committee to exhibit in full operation processes which have been worked out in Great Britain for the production of the lowest temperatures hitherto attained. Mr. J. E. Petavel, who was in charge of the apparatus, gave interesting lectures on liquid hydrogen and liquid air at frequent intervals, and large quantities of liquid hydrogen were produced regularly. On the occasion of the inspection of the plant by the International Jury, the largest quantity of liquid and solid hydrogen that had ever been made at one time was exhibited. The plant was erected in a separate building near the Liberal Arts Palace, while the lectures were delivered in the palace itself.

The greater part of the British exhibits in this section were arranged in octagonal show-cases, which not only enabled the articles to be seen to full advantage; but also gave an individuality to each exhibit which was sometimes lacking in the case of other nations. In mentioning some of the chief British exhibitors, I need scarcely enter into details as to the goods, because most of the firms are thoroughly familiar to us all. Heavy chemicals were represented by the British Cyanides Co., Ltd., The Gas Light and Coke Co., Ltd., who showed a fine collection of derivatives of coal gas, tar and liquors; the United Alkali Co., Ltd., with a very complete series of products relating to the alkali industry, ultramarine and recovered sulphur; Peter Spence and Sons had practically two exhibits—one of titanium compounds, now extensively used as a mordant in dyeing, and the other of alums and other aluminous compounds. Among the latter were some remarkably fine specimens of rubidium, thallium and caesium alums, which attracted much attention. The Anglo-Sicilian Sulphur Co., Ltd., the Cassell Gold Extracting Co., Ltd., the Castner-Kellner Alkali Co., Ltd., Chance and Hunt, Ltd., Spencer Chapman and Messel, Ltd., McDougall Brothers, the South Metropolitan Gas Co., and Jno. and Jas. White were all well represented, and obtained high awards. Pharmaceutical and fine chemicals fully maintained the high standard to which we are accustomed in this country, the chief exhibits being those of Burroughs, Wellcome and Co., Evans Sons, Lescher and Webb, Ltd., Hopkin and Williams, Ltd.,

Howards and Sons, Ltd., Corbyn, Stacey and Co., Ltd., May and Baker, Ltd., T. Morsen and Sons, Ltd., and Tyler and Co., Ltd.

As is usually the case in British exhibits, some of the products were very poor, but there being no special prizes by Edward Cook & Co., Ltd., Joseph Cross & Co., Ltd., J. C. and J. F. Ltd., Price's Patent Co., Ltd., Ltd., Barnard, O'Brien, Ltd., and W. & A. Ltd., pottery and glass tools were shown by Stuart & Son and Sons, Ltd., and Roake, Roberts and Co., Ltd. A good assortment of minerals was exhibited by Reed and Tateck, Ltd., John, J. Griffin and Sons, Ltd., and Towns and Merion. Among the scientific exhibits may be mentioned those of Sir W. P. A. Ramsay, F.R.S., who sent some unique specimens of helium, argon, neon, krypton, and xenon, also helium formed by the spontaneous decomposition of the radium emanation; and Sir J. W. Swan, F.R.S., and Mr. J. A. Kendall showed candles made from atmospheric nitrogen by the process upon which they have been working with great perseverance for several years. Dr. Ludwig Mond's gas producer was represented by a model, and Sir H. E. Ross's original preparations of vanadium attracted many chemists. A very striking exhibit was that of Levinstein, Ltd., in which a large number of dyed samples were arranged in book form. Brooke, Simpson and Speller, Ltd., and Read, Holday and Sons, Ltd., had exhibits of dyes of various kinds.

I have purposely refrained from entering into minute details of our British exhibits, not only because they have been fully described in the official catalogue issued by the British Royal Commission, but also because there have been many notices in the press in this country. In the case of some of the foreign firms, however, it may be of interest to give particulars of individual exhibits.

France occupied a site adjoining our own in the Palace of Liberal Arts. The exhibits were housed in tasteful showcases, all arranged on the same pattern. A special case was occupied by an important collective exhibit of the Société Chimique de Paris, containing products discovered by the members of that Society since 1900. Many of these were of great scientific interest, illustrating the recent researches of eminent chemists, such as Moissan, Mourou, Sabatier, Haller, Gaubert, Baillache, Béhal, Bertrand, Bouvenot and many others. M. A. Béhal, professor of toxicology at the Paris Ecole supérieure de Pharmacie, also had a separate exhibit full of interesting organic preparations, especially in the camphorine series, and a small library of works of which he is the author. Among the commercial exhibits, perfumery predominated, there being nine firms represented. The firm of Pinard had a fine collection of natural perfumes and toilet preparations, and M. L. Roure of Grasse, Alpes Maritimes, exhibited large quantities of extracts and pomades as used by perfumers. A new method of extracting the perfumes from flowers by means of a hydrocarbon solvent, instead of the usual process of enfleurage, was illustrated by models. One firm exhibited synthetic perfumes as such, but in most cases these appeared under the name of some natural perfume, or some special trade name. Pharmaceutical preparations were very well represented. The Pharmacie Centrale de France, represented by Chas. Buchet and Co., had a large selection of preparations of various kinds, about 700 tons per annum being given as the output from their various works. Among other firms showing similar products may be mentioned P. Astier, Chassaing and Co., G. Chevrier, Comar et Fils et Cie., E. Landrin, whose ibogaine is said to possess properties intermediate between those of kola and coca. It is prepared from the iboga root, grown in the Congo district. Among the synthetic remedies exhibited, "stovaine," made by Poulenc Frères, appears to possess valuable properties as an anæsthetic. It is said to be a chlorhydrate of dimethylaminodicyclopentanol, and to be much less poisonous than cocaine. The same firm exhibited a series of radioactive products derived from carnotite, and a fine collection of porcelain colours. The Société des Produits chimiques de Marseilles l'Estaque decompose salt by means of the gases from pyrites kilns; the residues from the pyrites are lixiviated, and about 4000 tons of sulphate of copper are

produced annually, while the sodium sulphate is converted into soda, or used as such by glass-works.

Glues and gelatines were well represented by six firms, of whom Rousselot et Cie., Laprêvotte et Cie., P. Collette and G. L. Borrel et Fils obtained the highest awards. An article made from gelatine, and well worth the attention of our manufacturers, is the sponges now used largely for dress decorative purposes. They are in increasing demand, and the quantities produced in France are very considerable. Among the special articles shown by manufacturers may be mentioned L. Bourdeau's fluorides and fluosilicates, Deschamps Frères' ultramarines, Louilleux and Co.'s printing inks and D. A. Bloeh's barium compounds.

Although heavy chemicals were not so well represented as in the British section, several large firms had good displays. Among them may be mentioned Corbin and Co., with a number of electrolytic chemicals, especially chlorates and perchlorates, together with wood pulp; Poulenc Frères, who had a large number of general and photographic chemicals, and Schloesing Frères and Co., with a display of sulphur and its derivatives. In the Palace of Machinery, Paul Kestner exhibited a number of models and drawings of chemical plant, especially evaporators and elevators.

In modern industry there is a great deal of make-believe, either artificial substitutes for natural products or new materials intended to take the place of older ones to which the public has become accustomed. Sometimes there is very little difference between the new product and the older one, and this was specially noticeable in an excellent exhibit of artificial rubies by P. A. Paquier. The appearance and colour of these brilliant gems were equal to those of the natural stones, and as the chemical composition is identical in both cases, the imitation can only be distinguished by optical methods. For watch-making purposes, these artificial rubies are being largely used.

Artificial silk is another material that imitates nature very closely in appearance, if not in chemical composition. The Société Anonyme pour la Fabrication de la Soie de Chardonnnet had a brilliant display of artificial silk goods indistinguishable in appearance from real silk. Exhibited for the first time in 1889, the Chardonnnet silk did not at first meet with much encouragement, owing to its inflammability, but when the denitration process had been worked out, progress became more rapid, until to-day the production of the Besançon factory is 3600 pounds daily. The number of employees is 1500, and the consumption of alcohol as a solvent is 25,000 hectolitres (550,000 gallons) annually. The collodion solution is filtered under a pressure of 60 to 80 atmospheres, and under the same pressure is driven through spinning nozzles 0.06 mm. in diameter. It is to be hoped that increased facilities for the industrial use of alcohol may enable this highly remunerative industry to be re-introduced into this country.

Germany also had a fine exhibit of artificial silk by the Vereinigte Glanzstoff-fabriken, of Elberfeld, who work according to Pauly's process, in which the cellulose is dissolved direct without previous nitration.

The German chemical exhibit was in the main a collective one, and the whole subject was treated more from the educational than the commercial point of view. The exhibit collection was installed in the Palace of Electricity; but other exhibits were dispersed throughout various buildings in a way that rendered it somewhat difficult to obtain a general impression of this section. Several fully-equipped laboratories were fitted up in a way that reflects great credit upon the organisers. The oldest was that of an alchemist showing the conditions under which men like Glauber, Scheele, Kunkel and Böttger worked, and the apparatus with which they laid the foundation of modern chemistry. Another reproduction showed Liebig's laboratory at Giessen, as it existed in 1835, and in the cupboards were many of the great master's original preparations. In view of the great interest aroused by such relics, one cannot but deplore the absence in this country of any organisation for preserving objects of interest to chemists. Apparatus and preparations that would be priceless to future generations may be had now for the

asking, and the cost of preserving them would not be great. Biologists carefully preserve their type specimens, and engineers are proud of the first efforts of a Watt or an Arkwright; chemists alone appear to forget that chemistry is no longer the despised handmaid of other sciences; but an independent branch of knowledge with a powerful influence on human progress. It ought to be possible for the chemical societies of the greatest City in the world to provide a room where relics that might easily be obtained from their members could be stored. Near the Liebig laboratory was a fully fitted up table of the Berlin University laboratory for inorganic chemistry, equipped with the most modern appliances. Among the mass of apparatus exhibited may be mentioned those for gas analysis of Winkler, Hempel, Bunte, Ferd. Fischer, Wohl, Göckel and Viktor Meyer, among the latter the original Berlin porcelain vessel in which the density of gases was tested up to 1800° C. The Berlin porcelain manufactory had a large exhibit of chemical vessels of all kinds, and Schott and Genossen an equally interesting collection of their well-known glass ware. Heraeus showed some fine platinum and iridium apparatus; but what attracted most attention was a number of quartz vessels of considerable size, one exceeding 250 c.c. Practical demonstrations were given of the fact that these quartz vessels could be heated red-hot and plunged into cold water without cracking. It is evident that this new material, upon which so much pioneer work has been done in England, will in the future play an important part in technical as well as in scientific chemistry, and it is to be hoped that our manufacturers will take steps to secure their share of so promising an industry.

The collection of German scientific apparatus in the electrical building was large, and was supplemented by another in the Palace of Agriculture having special reference to the teaching of agricultural chemistry and research work connected with it. The greater part of this collection was from the Vereinigte Fabriken für Laboratoriumsbedarf, who had about 180 exhibits. There were also special laboratories for pyro-chemistry, electro-chemistry, dyeing, physiological chemistry and fermentation and general and inorganic chemistry. In the Liberal Arts Palace was an exhibit of perfumery and cosmetics, organised by six firms collectively. The greater part of the large German manufacturers, especially of dyes and organic products, had combined to form a collective exhibit in which the individuality of each separate firm was merged. The collection was certainly an excellent one; but one could not help thinking that on the whole these exhibits did not do full justice to a trade employing 161,000 hands and producing goods valued at £50,000,000.

An excellent description of the German chemical exhibits at St. Louis was published in the *Chemiker Zeitung* of May 4th, 1904, by Dr. Walter Vieweg. To him and to Dr. O. Zwingenberger, who was in charge of the chief chemical collection, I am indebted for much useful information. Dr. C. Harries, of the First Chemical Laboratory at the University of Berlin, who was the general secretary of the German Chemical Exhibit, was kind enough to send me some of the photographs shown at this meeting.

Of two materials nature has granted a practical monopoly to Germany, namely, potash salts and amber. The former were well represented by the Stassfurter Chemische Fabrik, who exhibited a large number of potash compounds, both natural and artificial, together with bromine and magnesium chloride and sulphate. The firm employs about 500 hands. Amber mining is a monopoly of the Prussian Government, and as but little is known about it here, a few particulars may be of interest, especially as it is the raw material for the best varnish known.

Nearly the whole of the amber now produced is obtained by mining, the amber being contained in a layer of blue clay which yields on an average 3-25 kilos. of amber per cubic metre. The value of the product in 1902 was £79,962. America imported in that year raw amber to the value of £41,726, England only £2,416. A new industry has arisen having for its object the utilisation of the smaller pieces of amber. These are carefully cleaned, warmed to about 180° C., and forced through a fine strainer,

when they unite and form a homogeneous mass. In order to facilitate the use of the material to perfume the Government factories melt the amber by steam at about 375° C. This melted amber was sold for an amount of £13,872 in 1902.

Some excellent specimens of opal were exhibited from German East Africa; but it is to be feared that the population of that colony is at present too small to develop a trade in such a product.

The United States chemical exhibits did not occupy the important position which her chemical industries might have led us to expect. The exhibits were also sprinkled over different buildings, so that it was a work of much labour to find them. The only display that could be called a collective one was that of the United States Government, who had an analytical laboratory for food products in actual work. The experimental stations of the different States of the Union showed special laboratories and analytical results, chiefly in connection with agriculture; for instance, Louisiana had a sugar laboratory, and Wisconsin a dairy laboratory. There appears to be a very large business in chemicals used for spraying fruit trees and crops, a practice which is now so general in the United States, that most of the insect enemies of the agriculturist can be kept under control. The American horticulturist does not confine himself to grumbling at the insect pests which are so numerous in his country; he fights them energetically, and, with the help of the chemist, he generally succeeds in securing the safety of his crops for a very small expenditure per annum. In most modern books on fruit culture in America regular spraying of the trees is recommended. There were several exhibits of starch and glucose products; in fact, almost every article made from cereals was represented. The Californian wine industry appears to have reached the limits of the home demand, and considerable prizes are being offered by the associated grape growers for new uses for grape juice. Large quantities of unfermented grape and apple juice are now being sold in sterilised bottles, and the industry appears to be growing rapidly. There should be a good sale for apple juice in this country if properly prepared. California had a good display of olive oil and, of course, cottonseed oil was represented by many samples. Connected with the Forestry department was an exhibit showing a new method of collecting turpentine, which is said to produce larger quantities with less injury to the trees than the old method. The supply of turpentine from the long-leaf pine appears to be falling off, and other sources are being utilised. Considerable quantities are now made by distilling wood, and especially the roots of the pine trees, but the turpentine thus obtained differs in important particulars from that produced by distilling the exuded resin.

In this department were numerous displays of wax and honey; but as these have been dealt with fully in a paper published in the *British Bee Journal* of Jan. 5th, I need only mention them here.

Coming to chemicals generally, the best collection was undoubtedly that of the Mallinckrodt Chemical Works of St. Louis. Large masses of morphine, cocaine, strychnine, caffeine, and many other preparations to the value of thousands of pounds were tastefully arranged in a large show-case of special design. Another exhibit of the same firm showed the various alkaloids extracted from opium. The Roessler-Hasslacher Co. also had a large exhibit containing many sodium compounds, acetone, chloroform, formaldehyde and ceramic colours. Perfumery was represented by several firms, such as the Meller Drug Co., the Sanitol Chemical Laboratory Co., the Allan Pfeiffer Chemical Co., and W. R. Warner and Co.

Of special importance were the electrolytic products most of which were shown in the Palace of Mines and Metallurgy. The Castner Electrolytic Alkali Co. showed caustic soda and bleaching powder, and the Niagara Electro-Chemical Co. peroxide of sodium and metallic sodium. The Union Carbide Co. had a large quantity of calcium carbide and the Carborundum Co. not only showed a striking trophy of carborundum, but also a full-sized furnace as used in their works. The production of this material for 1903 was 2,125 tons. Fine samples of graphite made electrically were shown by the International Acheson

Graphite Co. In the same building was a very complete collection of mineral oils, paraffin, &c., by the Standard Oil Co., and a large exhibit by the Trinidad Asphalt Manufacturing Co. Of considerable interest was the sulphur from Cadeau in Louisiana, the average yearly production of which is between 15,000 and 16,500 tons, the whole of which is melted underground and brought to the surface through boreholes, the heating agent being superheated steam. Mr. Eustace Carey has given some interesting details of this deposit in his address to the Liverpool Section of our Society. In the same building was a very complete collection of most of the radioactive minerals known, and the search for others is being actively prosecuted in the United States. A walk through the Mines and Metallurgy Building could not fail to impress the observer with the enormous mineral wealth of the United States, of which only a small fraction has yet been developed.

Brazil played an important part at St. Louis; her exhibits in group 23, for instance, ranking second in point of number. One must admit, however, that most of these were indicative of industries in the stage of development and fostered by high import duties. Most of the products were medical and pharmaceutical, with perfumes and toilet preparations. Glue, matches, soaps and oils were also shown by several firms.

Belgium was represented by 18 firms, among whom may be mentioned Les Anciens Etablissements, F. Moimmen and Co., who had a good exhibit of paints, and Les Agglomérés réunis du Bassin de Charleroy who showed distillation products of coal. The five candle factories of Belgium were represented by two firms, and of the 18 match factories, which produce $5\frac{1}{2}$ million gross of boxes annually, but one sent samples.

Sweden made a better show in matches, which was her only exhibit in this section. The production of the Jönköping Company is 5 million boxes daily. As showing the enormous quantity of materials that this apparently insignificant chemical industry consumes, it may be mentioned that the production of this one firm in 24 hours would encircle the earth.

Japan also exhibited a number of matches, of which she produces about 27,000,000 gross of boxes annually. Lacquer and fireworks were the other chief exhibits in this section. One firm exhibited chemical apparatus in porcelain, and although the articles were not yet equal to the products of Europe, we may look forward to a rapid development of this industry in the future. In group 24 Japan had three times as many exhibits of paper as any other nation. A very interesting class in which there were many exhibits was that including sea-weed products. The vegetable gelatine known as kanten is made in large quantities, and is used not only as a food, but also as a stiffening agent.

Bulgaria had a good exhibit of otto of roses, which was shown by seven producers.

Italy was chiefly represented by alcohol, pharmaceutical preparations and a good display of sulphur by the Roman Society for Sulphur.

A few other countries might be included in the list, but I must pass on to some of the independent out-door exhibits, some of which were of considerable importance. As we have seen, the lowest known temperatures were produced by Great Britain and the highest temperature hitherto known was also developed at St. Louis by Professor M. A. G. Himalaya, of Portugal, one of our colleagues on the International Jury. He erected a large parabolic reflector for concentrating the sun's rays, and succeeded in obtaining temperatures far exceeding those of the electric arc. In fact, the exceedingly high temperature has limited Professor Himalaya's researches, as every known substance is volatilised. The whole structure was about 40 ft. in height, the framework being V-shaped. There were 6,000 mirrors of silvered glass, each about 5 in. by 4 in., and the whole was mounted on a universal joint so that it could be turned towards the sun. Although such an apparatus might be seldom available in our climate, yet it was very effective in that of St. Louis, and might be useful in some of our Colonies.

Throughout the grounds of the Exhibition were numerous practical demonstrations of various manufacturing operations, especially those relating to metallurgy.

There was also a fully equipped laboratory of the American Cement Union, in which tests of cement were made daily. A very elaborate and complete series of tests were also made with different kinds of coal, a carload being used in each case.

The last installation to which I will refer was a large one for the manufacture of hydrogen gas for the purpose of inflating the balloons which took part in the aeronautical competitions. The process employed consisted in decomposing steam by red-hot iron turnings, which were then de-oxidised by means of producer gas. Partly owing to defective design, and partly to the lack of careful analytical supervision, the working of the apparatus was unsatisfactory, although ultimately a number of balloons were inflated.

In conclusion, I wish to thank the British Royal Commission, and especially Colonel C. M. Watson, C.B., C.M.G., the British Commissioner at St. Louis, for enabling me to obtain some of the information which I have summarised in the foregoing remarks.

DISCUSSION.

Sir JOSEPH SWAN said that the position occupied by England in the Exhibition was a great gratification to him. He confessed to having at one time entertained fears that they would look very small indeed as exhibitors. They owed very much to the energy and patriotism of the chemical members of the Commission and the assisting committee. In the last Report of the Commission there was given a telegram from the President of the United States to the King, wherein the President spoke of the British exhibits in the most complimentary terms, and he could not help thinking that he must have derived his impression of their excellence very largely from the Chemical Section. Many of the things referred to in the paper one would like to hear more about. For example, there was that curious apparatus for concentrating the heat of the sun, and he would ask Mr. Reid if he saw it in operation, and if he thought that the apparatus had any practical utility. He should also like to hear what his impression was of the uses of some of the novel exhibits he had referred to, such as artificial graphite, and if there was anything remarkable shown in that exhibit in size or form. In connection with the chemical uses of electricity at Niagara, did the Exhibition show any progress in the economical production of nitrates from atmospheric nitrogen, or other electrically produced chemicals of importance?

Mr. DAVID HOWARD said they had heard from many quarters that the exhibit was worthy of English industry, but whether it would ever pay any of those who took part in it in £ s. d. he did not know. He did feel, however, that it was of high importance just now, when they so often found people decrying all English industry and English efforts, and when in influential circles it was supposed that if a particular thing was foreign it must be better than if it were English. There was no doubt that it was of the greatest importance to watch most carefully all that was going on. Many of these new processes of which they had heard might prove to be of the greatest interest, and it was only by constantly watching what was going on that they could possibly keep abreast of the times.

Mr. HELM said he could thoroughly confirm Mr. Reid's statement that the English exhibit, as far as it went, was a splendid one. There were some articles there from other nations which he should like to see exhibited by England on other occasions, and he hoped that the duty-free alcohol Committee, of which they had heard so much, might lead to English manufacturers being in a position to exhibit artificial silk, and also some of the finer chemicals in which at present they did not show to much advantage. Mr. Reid had mentioned that the low temperature apparatus was the best of the British exhibit, but he had heard it said by many that it was the best exhibit in the entire Exhibition. Mr. Howard had raised the question whether exhibits of this kind paid an exhibitor. It was his firm opinion, from what he saw there, and what he had seen at Paris, that it would pay, not only the British exhibitor, but the British nation,

for going to the expense incurred. He only hoped it would lead to greater liberality on the part of the Government in the future. The British nation had no reason to be dissatisfied with what had been done, but the St. Louis Exhibition showed that there were still heights to which they might attain, and which he hoped they might reach in the future.

Mr. R. J. FRISWELL said that he should like to hear a little more about the apparatus for concentrating the sun's heat. Mr. Reid had spoken of a heat greater than that of the electric arc being obtained there. It was his lot some years ago to be engaged in an investigation of the sun and solar physics generally, and it was pretty generally held then, that the temperature of the surface of the sun was not greatly hotter than the temperature of the electric arc, and, therefore, it was difficult to see how such an excessive temperature could be obtained. He thought the explanation lay in another direction. In the electric arc the focus—the actual heated point—was extremely small, and radiation from it, of course, prevented maximum effects being seen in any kind of apparatus where the products could be obtained, and the reactions studied; whereas in the case of this vast reflector the focus was so large that losses due to radiation were comparatively small, and they got the real effects of a temperature such as that given by the electric arc.

Mr. T. TYRER said he should like to supplement from actual observation, one or two of the points to which Mr. Reid had referred. Mr. Reid had had a very difficult task before him in trying to give them an adequate idea of the vast Exhibition, which was far too big for anyone to master who went in any other capacity than that in which he and his colleague went, as jurymen. He must say with confidence that all the exhibits were adequate both to the position of the nation and of the individual exhibitors. There was fault found, however, not with the way the exhibit was put up, not with the extent of it, but it was called by some, old-fashioned. The range of British chemical industries, he admitted, was not quite as wide as some hoped for, and there was a conspicuous absence of organic products. There were many reasons for that. He was not going to anticipate the Report of the Industrial Alcohol Committee, but he had no hesitation in saying that if ever the details, the evidence, and the questionings of that Committee were printed, it would be one of the most interesting volumes which had been published for many a day. It would not show the inadequacy of the British chemists or analysts to tackle the questions before them, or the impossibility of conducting a wide class of industries under British conditions. Conditions considerably altered cases. A great deal had also been said about want of alcohol, and on that question he had on two occasions, in that place, given his views so strongly, that he had been called an agitator: but he had not modified his views in the slightest. There was no doubt whatever, that the so-called agitation about the defects of even the latest Patent Law was perfectly justified; even more than that upon the alcohol question, and education, both secondary and technical, had a good deal to do with the question of progress. He quite agreed with what Mr. Reid had said about the British, French, and American exhibits. In the German department there was the usual collectivity, without any marked indication of individuality. He had perused the German Educational Exhibition catalogue, and he found page after page full of the particular exhibits of the chemical products of the laboratories of the professors in the various towns. These exhibits covered a wide range of synthetic, pharmaceutical, dyes, intermediary and other products. He had studied the catalogue, and as germane to the great question in which some took an interest, he might say that his impression was that, in four-tenths of the whole, whether looked at as scientific products, or as coming near to, and in many cases being, technical products, alcohols, ethyl and methyl, were at some stage an absolute necessity. He again made this statement publicly, because it had been stated in print that the statement that alcohol was so largely necessary was not correct. He would conclude by saying that two pieces of literature would well repay study by any member of the Society, namely, the German

Chemical Catalogue, translated into English, and the Catalogue of English chemical exhibits, with an admirable introduction. In these would be found much of interest, which would amplify very largely and usefully, the description which Mr. Reid had given them.

Dr. J. LEWKOWITZ said he was surprised that the author had not mentioned the Society of Chemical Industry, as without that Society there would have been no chemical exhibition at all. He asked whether the author was in a position to state who was the designer of the octagonal cases which showed off the chemical exhibits to such great advantage. As he (the speaker) had been in St. Louis, he might be allowed to touch on some points with a view to eliciting further information. Thus they might be glad to hear something about the art exhibits in the Agricultural Department in the shape of frozen butter. One of the novelties at St. Louis was the Cowper-Hewitt light. He was told the Westinghouse people employed it extensively in their drawing offices. Use of this light was also made at the Exhibition by photographers, but the photographs were not very pleasing. He did not agree with the frequently expressed view that visiting an exhibition was a waste of time; he thought that an enormous amount of information could be gained thereby. The bottles in the Chemical Department spoke their own silent language, which became very eloquent if one had an interpreter like Mr. Reid to explain. He should have liked to hear something about the question of power. Those who had visited the Paris Exhibition of 1889, would remember the great machinery hall, which was filled with reciprocating steam engines. A great revolution was observed at the Paris Exhibition of 1900, all the machinery being worked by electricity, and there were not wanting people who predicted that the steam engine would soon be put into a museum. But threatened people live long, and in St. Louis one saw as the latest development of the steam engine the turbo-generator. Those who had been on the round trip with the Society had seen the anatomy of the Parsons' turbo-engine in the Westinghouse works at Pittsburgh. In the Exhibition itself he had observed the great machines exhibited by the Westinghouse Company, and the turbo-generators made by Curtis. This was very important to chemical manufacturers, as these engines were the latest development in the generation of power, again bringing forward the steam engine in a modified form to its old rank. Rumours would have it that there would be an exhibition in Paris in about 10 years. Might one hope to see there a further development in the turbo-generator, namely, a reversible one—a consummation which had not as yet been reached?

Mr. OSCAR GUTTMANN said that the manufacture of what was now called block amber, namely, a substance resembling amber and made by pressing the leavings and cuttings, was really devised with his advice. He was consulted about it 12 years ago by the firm of Stantien and Becker, the predecessors of the Prussian Government in the ownership of the mines, and he remembered the first specimen made looking almost like tortoise shell, the cloudy part being burnt brown. The great difficulty was to produce the cloudiness since all amber, when compressed hot, became uniformly translucent. They first tried to do it by means of precipitated magnesia. Then they took ambers of varying hardness, with and without other resins of different melting points, and thereby obtained finally the optical effect on which the cloudiness depended.

The CHAIRMAN said with regard to the question of whether or no it paid manufacturers to exhibit, he thought it would sufficiently have paid if they had succeeded, as they might claim to have done, in demonstrating that Great Britain had not got behindland in chemical industry, but still held a foremost position notwithstanding all that had been suggested to the contrary. The exhibit which had been made might possibly not be as full or as comprehensive as it was possible for this country to make, but undoubtedly it was one of which they need not feel ashamed. How was it that with the American tariffs against them, and with the feeling of opposition against

exhibitions in general, they were able to get that collection together, and how would it be possible to improve in the future? An appeal was made by the Royal Commission to the patriotism of all manufacturers, requesting them to put forth their best efforts to make a display worthy of this country. They concerned working on these lines, but they found it practically useless without one important addition. There was plenty of patriotism, but it was necessary to subsidise it; and when the Government consented to make them, through the intervention of the Royal Commission, a sufficient grant to cover the necessary expenses of exhibiting, imitating in this respect the example of Continental countries, without unduly taxing the pockets of the exhibitors, then and then only did success become possible. Without that sufficient grant they would never have succeeded as they had done. If that lesson could be taken to heart, and improved upon in the future, he was perfectly sure no one would say that England was not efficiently represented, either in chemistry or in any other branch of industry. But in addition to this, once having obtained the means and having got several willing helpers, it was necessary to pay personal visits to the manufacturers in the districts in which they resided, and fully explain the scheme of the exhibit. Manufacturers with few exceptions would not come up to London to inquire about the matter, nor would they attend to printed forms of application for space which were sent to them. It was necessary in addition to visit them, and bring pressure to bear on them to exert their energies. He would mention one other point in connection with a successful display. A most essential feature in connection with the display was to rehearse the exhibits previous to sending them over. That went to the root of the success of this exhibit. All the cases were filled in this country prior to being sent; there was a number to each bottle or specimen, and a photograph was taken of the exhibit as it was intended to be installed, so that after its arrival a competent man could fill the cases, and there was no difficulty whatever in re-producing the wishes of those who had contributed. A remark had been made respecting the display of the professorial establishments in Germany; but he thought if anyone would take the trouble to look into the catalogue of the British chemical display, they would find that on this occasion the professors of Chemistry in Great Britain were certainly well to the front, and exhibited many specimens, which were not only of historical interest, but also showed that they were well alive to the requirements of chemical industry. Finally, with regard to the remark of Dr. Lewkowitsch that reference should have been made to that Society, he would venture to point out that the whole country knew perfectly well that that Society was the backbone of chemical industry in this country, and that no exhibit of chemical products could have been made unless it had obtained the full and loyal support of its members. He did not think there was an exhibitor of chemicals who was not a member of the Society. It should, however, be remembered that the Society was not represented officially as such, but only through the members who took part in the work of organisation and the exhibitors who so materially advanced the interests of the industry by their invaluable co-operation.

Mr. W. F. REID, in reply, said he had forgotten to mention that there were 110 exhibitors in the British Chemical Section, 100 of whom obtained awards, which he thought was a highly satisfactory result. With regard to the question as to the solar concentration apparatus, he might say that Prof. Humalaya had told him that he had tested the temperature by all the means with which he was acquainted against the highest temperature he knew of in the electric arc, which he believed he put at 2500° C., but, of course, it was quite impossible at such temperatures to obtain the exact value. The results he had obtained were such as could not be produced in the best electric furnaces. With regard to the practical utility of such apparatus, it was very difficult to say how far it might be used for practical purposes. He believed some small solar mirrors were at work in which a boiler was placed in the focus, and in Algeria and other places where the sun was strong, they were useful. It had been worked at since 1896. Artificial graphite could now be obtained

in very large pieces, and he had worked with these as anodes for some time. With regard to the fixation of atmospheric nitrogen in the production of nitrates at Niagara, the nitrates were not exhibited to claim an award, but he heard that the apparatus was getting beyond the experimental stage, and that it was actually producing quantities which might be called commercial. Beyond that he could not go, because it was not yet on the market, and some very high authorities claimed that nitrates could not be made economically by this process. He had recently received a letter from St. Louis which might be interesting to traders as bearing on the question of the utility of such exhibits. The following was an extract:—

"All the representatives of the Government Institutions I have seen lately have said, Why do not your exhibitors send us their price lists and quotations, for instance, all our fine reagents we have to buy abroad from Germany, and we would rather trade with England. We are large consumers, good payers, and we have no duties to pay." Probably those in the trade might know more about it, but it seemed to him that to send circulars to those interested might be of some use. Mr. Helm's statement that the low temperature exhibit was the best chemical one in the whole exhibition was quite correct, although the Mallinckrodt exhibit was the best display of chemicals. He might say he cordially agreed with Mr. Tyrer on such questions as education, free alcohol, and most of the other points he mentioned. As to the German literature, that was very well done indeed. There was only one nation which worked out the literature more perfectly in some respects, and that was Great Britain. With regard to Dr. Lewkowitsch, he felt he must accept his reproof. He ought certainly to have mentioned, what the Chairman had now done, the part the Society played in the question, but perhaps it was so obvious that it was hardly necessary to refer to it. With regard to the octagon cases, the first idea he heard of them was from Mr. Tyrer long before they came into being, and he was told that the idea came from the form of an elevator on the Underground Railway. With regard to the butter statuary, it was really very beautiful, and as a member of the Jury he had an opportunity of ascertaining that it was really butter. Of course, precautions were taken to keep a sufficiently low temperature. The Cowper-Hewitt mercury light was used a great deal at St. Louis. With regard to power he certainly might have mentioned the latest advances in that direction, but he had already referred to the subject in the paper which he recently read before the Society of Arts. Mr. Guttman's name was not mentioned in connection with the amber, and he did not know that he had been associated with this development of the amber industry. He got the whole of his information from the official description of the industry, and he met the geologist in charge of it who told him that the cloudiness in the amber was attributed to the juice of the tree—the original sap—getting mixed with the resin at the time of exudation, and they had tried to put some kind of moisture into the amber in order to produce this cloudiness in compressing it.

ENGLISH PATENTS.

Superheating Steam; Apparatus for —. A. Bolton, Manchester. Eng. Pat. 26,822, Dec. 8, 1903.

THE invention relates to the class of superheaters described in Eng. Pat. 6459, of March 17, 1902. An improvement is effected by dividing the superheating box into three compartments by means of an arched diaphragm, two of the compartments acting as inlet and outlet for the steam, whilst the third acts as an intermediate chamber. Holes are drilled through the arched diaphragm, and tubes open at both ends inserted in these, corresponding holes, but of larger diameter, are drilled in the bottom of the box plate, and other tubes, closed at the bottom end, inserted through these to surround the first tubes. Each row consists of tubes of different diameters, the larger tubes being placed behind the smaller ones in a direct line, or in zig-zag fashion.—L. F. G.

Semi-liquids; Means for Drying —. A. J. Oxford, Walton-on-Trent, and S. H. Buxton, Burton-on-Trent. Eng. Pat. 28,087, Dec. 22, 1903.

INSIDE a closed heating chamber is placed a pan, into which the semi-liquid is conveyed from outside, and from which it is distributed to various troughs. Each of these troughs abuts against the exterior of a revolving cylinder which in revolving spreads out upon its surface the liquid, which soon dries up there. The surface of the cylinder thus soon becomes encrusted, and the dried matter is subsequently scraped off and collected by suitable means. The top of the chamber enclosing the pan, drying cylinders, &c., is provided with a flue with regulating damper.—L. F. G.

Drying and otherwise Treating Materials by Air and other Currents; Process and Apparatus for —. H. H. Lake, London. From E. N. Trump, Syracuse, U.S.A. Eng. Pats. 28,594 and 28,595, Dec. 29, 1903.

SEE U.S. Pats. 748,894 and 748,893 of 1904; this J., 1904, 111.—T. F. B.

Centrifugal Separators; Impts. in —. R. H. Haylock, London. Eng. Pat. 2792, Feb. 4, 1904.

THE claim is for an improved type of separator for separating water, dust, soot or oil from air, or other gases. The gases are led tangentially into a vertical cylindrical

chamber provided with a conical bottom with the apex uppermost, and the solid particles separating are drawn off through an outlet placed at the circumference of the bottom. A vertical pipe passes through the top of the cylinder and projects some distance inside, and the purified gases escape through this. The sides of the chamber may be provided with spiral ribs, and liquid may be sprayed in to facilitate the settling of solid particles.—L. F. G.

Filtering Liquids; Apparatus for —. W. Reeves and B. Braumwell, Belfast. Eng. Pat. 3050, Feb. 8, 1904.

THE filtering apparatus consists of a spherical chamber mounted on two hollow trunnions. Through one trunnion passes the inlet-pipe for the liquid to be filtered, and projects to some suitable height inside the chamber. Through the other trunnion passes the delivery pipe, which communicates with the bottom of the chamber, and above which is placed a bed of filtering material. The liquid enters through the inlet-pipe, flows through the filtering material, and away through the delivery pipe. To clean the filter-bed, a cleansing liquid is admitted, and the chamber revolved on its trunnions, the particles of the filter-bed then fall through the liquid and get washed.—L. F. G.

Filter Press Plate. C. A. Allison, London. From the Niles-Cement-Pond Co., Jersey City, U.S.A. Eng. Pat. 23,942, Nov. 5, 1904.

SEE U.S. Pat. 776,024 of 1904; this J., 1905, 20.—T. F. B.

Registering by Electrical Means; the Progress of Several Physical Processes; Apparatus for Automatically —. Siemens Bros. and Co., Ltd., London. From Siemens and Halske, Berlin. Eng. Pat. 17,528, Aug. 11, 1904.

THE pointer of an electrical measuring instrument is provided with a marking style, which registers the position of the pointer upon a band of paper at certain regular intervals of time. By means of suitably arranged contact wheels, the electrical measuring instrument is connected successively to one of several circuits; the several physical processes being related to those separate circuits. The application of the apparatus to the case of electrical pyrometers registering the temperature of several furnaces is described.—B. S. H.

UNITED STATES PATENTS.

Heating Fluids; Apparatus for —. B. W. Davis, Phillips, Wis. U.S. Pat. 777,083, Dec. 13, 1904.

A COIL or vertical series of communicating inclined

sections is so arranged that the highest part of one convolution or section is situated in a horizontal plane above the plane in which the lowest part of the convolution or section next above is situated. The whole is surrounded by a heating chamber. The liquid enters the coil at the top and is drawn off at the bottom, flowing in the opposite direction to that in which the heating medium flows.—W. H. C.

Multiple-Effect Evaporating Apparatus. S. M. Lillie, Philadelphia, Pa. U.S. Pat. 777,114, Dec. 13, 1904.

CLAIM is made for the combination of three or more horizontal and parallel units or "effects," which have the steam-chambers of adjacent "effects" at opposite ends, with valved passages between the steam and evaporation chambers of adjacent "effects." Valved pipes are arranged to supply the heating agent to the steam-chambers and the liquid to be evaporated to the vapour-chambers at either end of the series, and condensers for the evolved vapours, and valved outlets for the concentrated liquid are also placed at either end. The liquid flows through the series in one direction and the heating agent in the other. The vapour from one or more "effect" may be taken to the steam-chamber of the next. The arrangement in which the steam enters the hottest and the vapour leaves the coolest effect is also claimed.—W. H. C.

Concentrator for Solutions. J. U. Lloyd, Norwood, Ohio. U.S. Pat. 777,115, Dec. 13, 1904.

A CONCENTRATING tank has a heating coil therein, and a cooling coil situated beneath the heating coil, the supply of heating and cooling media for the heating and cooling coils respectively, being controlled by valves. A series of "steeping tanks" is combined with the concentrating tank and a condenser, vapour-pipes leading from the concentrator and steeping-tank to the condenser, and return liquor-pipes from the condenser to the concentrator and steeping-tank, and from the bottom of the steeping-tank to the concentrator. Steam is supplied to the coils of the concentrator and to the steeping-tank by independent connections, controlled by valves.—W. H. C.

Drier. J. Scott, Assignor to E. P. Mueller, Milwaukee, Wis. U.S. Pat. 777,225, Dec. 13, 1904.

IN a drying chamber are arranged vertical series of rows of horizontal, perforated pipes, closed at one end, the other ends extending beyond the chamber and opening into an adjacent chamber supplied with hot air. Through the walls of the drying chamber, rods extend, carrying at their ends reciprocating rakes, the teeth or blades of which hang down between the perforated pipes. The feed hopper has toothed feeding rolls which as well as the rods of the reciprocating rakes are worked by a system of gearing situated outside the chamber.—W. H. C.

Gaseous Mixtures; Process for the Separation of —. C. Clamond. Fr. Pat. 346,195, Sept. 12, 1904.

This method for the separation of gaseous mixtures consists essentially in passing the mixture under pressure through a tube, and then periodically interrupting the flow. The periodic interruptions throw the mixture into waves or zones, one zone being rich in one gas and a second rich in another gas. During the period of repose, or near to this period, each gas is extracted by taking it from the zones in the tube where it is separately accumulated. The separation is brought about by the different kinetic energies of the particles of the gas, caused by the different densities of the constituents. The form of apparatus is also claimed and consists of a first interrupter or tap, which is turned so as to bring about the periodic interruptions in the principal column of the gas. One or more interrupters or taps are also turned and act alternately with the first, that is to say, while the first is open the others are closed and alternatively. The latter taps permit of the escape of the gases from the zones of the pipes where they have accumulated, and a separation of the gases is thus effected.—B. N.

II.—FUEL, GAS, LIGHT.

Gasification of Vegetable Combustible Matters and Generation of Economical Motive Power for Agricultural Purposes. L. Bordenave. Comptes rend., 1904, 139, 1046—1048.

THE author has carried out experiments at Menier's works in Noisiel, on the utilisation of various vegetable substances, such as straw, leaves, sawdust, &c., in the production of gas for use in motors for weak gas. Farmers as a rule obtain the power they require from coal, consumed in locomobiles or fixed motors, the quantity of fuel required, and the net cost, being respectively 3.4 kilos. and 20.30 centimes per effective horse-power-hour. The author finds that a great saving in cost would result if the coal were replaced by the said waste vegetable substances gasified in a generator provided with a reducing column of vegetable charcoal or coke (compare Eng. Pat. 27,533 of 1902, this J., 1903, 411), the weak gas generated being consumed in suitable motors; and the favourable results obtained in his experiments point to the advisability of establishing central power-stations, each capable of meeting the requirements of a certain number of farmers, using 40.50 h.p. or more. In the experiments, a 70 h.p. installation, comprising a generator and a motor of the kinds mentioned above, was employed, the results being as follows:—(1) Inferior hay, from marshy meadows. Consumption per h.p. hour, 1.02 kilos. Calculated net cost per h.p. hour, 5.6 centimes. (2) Wheat straw. Consumption, 1.05 kilos. Net cost, 6.3 centimes. The net cost, using oat straw, was 5.7 centimes. (3) Fallen beech leaves. Consumption, 0.59 kilo. Net cost, 4.3 centimes. Chestnut and plane-tree leaves gave practically the same remarkable results. (4) Sawdust and shavings. The net cost per h.p. hour was about 5 centimes, the consumption being 1.80 kilos. in the case of sawdust, and 1.35 kilos. in the case of shavings.—H. B.

Coke and Gas; Manufacture of —, the Construction of Coke-Ovens and Gas-Retorts, and the Recovery of By-Products from same. J. T. Key, Fencehouses, Durham. Eng. Pat. 576, Jan. 9, 1904.

THE coke-ovens are constructed upon iron foundations supported upon columns, and are provided with removable bottoms, which can be lowered upon carriages, running on rails, and pushed aside when the ovens are to be discharged. The ovens may be otherwise of the beehive type; or they may be surrounded by a space in the brick-work, into which the gases liberated are led and burned along with air to maintain an intense heat within the oven; or, again, the products of the distillation may be led off for the recovery of ammonia, &c., and the washed gas led back to be burned with air in the heating space, as just described. The arrangement may be used as a gas retort, by reducing the height of the carbonising chamber and using producer gas as the combustible in the heating space. —H. B.

Coke; Method of Producing Superior —, in Connection with Gas Works and the like. J. R. Breckon, Sunderland. Eng. Pat. 24,293, Nov. 10, 1904.

COAL is placed in suitable ovens provided with flues in the sides, through which a burning mixture of gas and air circulates. The gas given off during coking is led to the main gas-pipe of the works, and the ordinary means are provided for charging and for drawing the coke.—L. F. G.

Liquid Hydrocarbons; Burning of —. P. and F. P. Davies, Southfields, Surrey. Eng. Pat. 27,361, Dec. 14, 1903.

ONE or more atomising burners discharge the liquid fuel into the larger end of an open truncated cone, wherein it is ignited, the flame issuing from the further end of the cone in the form of a tongue. For certain purposes, where a gentle flame is required, an attachment is fitted on the narrow end of the cone, consisting of a hollow bulb terminating outwardly in a short open cylinder and fitted with an internal cone serving as a deflector, the point of this cone being turned towards the burner nozzle. —C. S.

Liquid Fuel; Apparatus for Burning —. P. and F. P. Davies, Southfields, Surrey. Eng. Pat. 27,362, Dec. 14, 1903.

THE invention comprises an initial starter, formed of a steam generator enclosed in a casing, which serves as a combustion chamber, and heated by a burner or feeder connected with the steam space of the generator. Similar connections lead from this steam space to the main burner. Air for supplying the starter is pumped into the water space in the generator and passes through the connections leading to the starting burner, where it atomises the liquid fuel.—C. S.

Burning Liquid Fuel; Apparatus for —. W. Cunningham. Eng. Pat. 25,706, Dec. 18, 1903 (under Sect. 2 of Pat. Act., 1888).

AN oil-supply pipe is led through an annular chamber, and is connected by a U-joint to a vertical tube leading downwards and through the chamber, the lower end of this tube being furnished with a cap, for cleaning purposes. A horizontal pipe leads from this tube to another U-tube, which again passes downwards into the annular chamber, and is also capped. Another horizontal pipe leads from this to a similar U-tube, which terminates with an open end in the chamber. Air is forced through the central hole of the box, and passes through another U-tube into the chamber. The mixture of oil gas and air escapes from the annular chamber through a series of holes arranged round the central hole, becomes ignited, and heats the U-tubes so as to vapourise the oil contained in them. The apparatus is started by making a small fire in the centre among the

tubes by means of petroleum spirit or shavings. Regulating devices are provided, and the apparatus can be adapted to a furnace. It is claimed that the apparatus can be very easily cleaned on becoming choked.—L. F. G.

Carbonic Acid; Production of — [from Gases of Combustion]. G. A. Schütz, Wurzen, Saxony. Eng. Pat. 25,867, Nov. 26, 1903.

A STEAM boiler containing water, as pure as can be obtained, is heated by a coke fire, and the steam is employed to drive a non-condensing engine. The gases of combustion of the coke fire, pass first into a scrubber, filled with coke and sprayed with cold water, whence they are pumped into a similar tower, down which warm water trickles. The heated and moistened gases then enter the bottom of an "absorption tower" filled with coke, on to which a cold solution ("lye") of sodium or potassium carbonate trickles, and absorbs the carbon dioxide and moisture in the gases. On subsequently heating the alkaline liquid by the exhaust steam from the engine, carbon dioxide is set free and collected, and the steam is condensed, and thus "the whole of the necessary purified water for the steam boiler, is continuously produced by the apparatus itself." (Compare Fr. Pat. 323,554 of Aug. 7, 1902; this J., 1903, 495).—E. S.

Gas; Manufacture of —, and Producers therefor. E. Schweich, London. Eng. Pat. 26,596, Dec. 4, 1903.

IN working a gas producer by downward draught, a supplementary supply of fuel and a supplementary air-, or air- and steam-blast is introduced into the lower part of the producer, for the purpose of maintaining a lower zone of combustion in which there will always be ample fuel present to combine with the oxygen of the air admitted thereto. The producer described, comprises a large central chamber and two small side chambers, the former extending above the side chambers and opening at its lower end into a space common to the three chambers. All three chambers are provided with fuel hoppers and blast inlets. The central chamber acts as the down-draught producer.—H. B.

Gas Producers. L. Mond, London. Eng. Pat. 28,031, Dec. 21, 1903.

THE producer described in Eng. Pat. 12,440 of 1893 (this J., 1894, 938), in which an "iron cylinder in the form of a truncated cone" extends downwards from the fuel hopper into the producer, is modified by providing openings in the cylinder, through which gases and vapours may pass without descending into the incandescent fuel. The openings may be fitted with adjustable slides or flaps, to permit of varying their size at will. The wider the openings, the more fluid is the tar obtained from the producer, and *vice versa*.—H. B.

Coal Gas; Manufacture of —. J. Y. Johnson, London. From the Deutsche Continental Gas-Ges., and J. Bueh, Dessau, Germany. Eng. Pat. 1393, Jan. 19, 1904.

SEE Fr. Pat. 339,534 of 1904; this J., 1904, 709.—T. F. B.

Water Gas; Manufacture of —. L. Guénot, Paris. Eng. Pat. 11,195, May 13, 1904. Under Internat. Conv., May 14, 1903.

IN the process described, the changes from the "make" to the blast periods, and *vice versa*, are effected automatically by the rise and fall of the gas-holder. The producer is provided at its lower portion with two air-inlet pipes, and at the top with an outlet pipe leading the waste gases to a chimney, these three pipes being controlled by water-sealed bells attached to a frame which is suspended from one end of a balance-lever. When the lever rises, the air inlets and the waste-gas outlet are opened simultaneously, and the draught of the chimney draws air through the fuel. In the upper part of the producer is arranged checker-work which is heated by the waste gases, and at the bottom is an outlet for water-gas, communicating with a gas-holder. When the balance-lever falls, the three pipes mentioned above are closed, water is admitted from above on to the hot checker-work, and the steam generated, on passing down through

the fuel, produces water-gas which flows out at the bottom to the gas-holder. From the other end of the bell in the lever is suspended a small tank, connected by flexible tubing with a small tank on the top of the gas holder. When the latter rises, water flows from the small tank into that suspended from the lever until at a certain point the lever is caused to swing down, stopping the water supply to the generator and opening the air inlets and water-gas outlet. The successive periods are thus controlled by the movement of the gas-holder, and the quantity of water-gas produced is regulated by the consumption. To prevent excessive prolongation of the blast period, a thermostatic device is connected to a damper in the chimney, and closes it more or less completely if the temperature of the waste gases rises too far.—H. B.

Producer with Free of Tar, and of High Burning Power, and of Fuel: Process and Apparatus for obtaining —. A. Desgraz, Hanover, Germany. Eng. Pat. 24,333, Nov. 10, 1904.

Into the space above the fuel in a down-draught producer there is fed a mixture of producer gas (or other combustible gas) with an excess of heated air, the combustion of which generates the heat for starting and maintaining the combustion of the fuel fed into the producer. The apparatus used may consist of a main producer and an auxiliary producer, the latter furnishing the gas required for admission to the main producer, the wall which separates the two producers being provided with passages through which the air supply flows and becomes heated.—H. B.

UNITED STATES PATENTS.

Coal Briquettes: Process of Making —. J. W. Barnes, Assignor to C. G. Hobson, Philadelphia, Pa. U.S. Pat. 778,096, Dec. 20, 1904.

GRANULATED coal, molasses and water are mixed together in certain proportions, formed into briquettes, and dried at a temperature of 280–300° F. They are then sprinkled with a mixture of paraffin and hot water, and again dried.—L. F. G.

Hydrocarbon Furnace. E. W. Jackson, Sansalito, Cal. U.S. Pat. 777,786, Dec. 20, 1904.

THE furnace (see figure) consists of a hollow base provided with upturned hollow hoods, through which pass oil-supply pipes ending in horizontal extensions. A revolving retort is loosely mounted on these extensions, its extremities being of larger diameter than the extensions so as to permit the vapours to escape. Air enters the hollow base through an opening in the bottom, and is blown through the hoods against the escaping vapours.—L. F. G.

Gas-Generating Apparatus. W. H. and G. E. Russell, Jersey City, N.J., Assignors to Internat. Gas Power Co., New York. U.S. Pat. 777,545, Dec. 13, 1904.

THE apparatus consists of a generator, in which a mixture of hydrogen and air is produced, a carburetter through which the gaseous mixture passes, a pump and reservoir for the supply of carburetting liquid, a filter for the carburetted gas, and a gasholder. The hydrogen generator comprises a reciprocating bell, working in an annular water-seal in an open double-walled tank, an open-topped copper vessel standing in the tank under the bell, a per-

forated copper holder suspended from and insulated from the crown of the bell and depending into the open-topped vessel, a spring contact between the latter vessel and the copper holder, a pipe for admitting air to the generator when the bell ascends, and an outlet pipe leading the gaseous mixture to the carburetter.—H. B.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

Tar: Continuous Distillation of —. O. Löw-Beer. Z. angew. Chem., 1905, 18, 8–11.

THE author states, as the result of practical experience, that the Lennard continuous tar-distilling plant has been so improved, that it differs in many respects from the apparatus originally patented (Eng. Pat. 844 of 1891; this J., 1892, 151). A diagrammatic plan of the process is shown in the figure. The cold tar is forced by means of the pump B first through a sieve which retains solid impurities, and then through the tube c into the condensers T and H, where it serves as a cooling liquid, and becomes heated to

a sufficient degree to give off the ammoniacal water it contains and a portion of the light naphtha. The heated tar passes next through the tube d into the "tar scrubber" E, which consists of a tower packed with fire-brick rings. At the beginning of the process, before the condensers T and H are in operation, the scrubber E is heated by means of superheated steam. The ammoniacal water and light naphtha from E are condensed in E, and pass to the tanks P P. The dehydrated tar then passes to the hot tar reservoirs Q Q, any volatile products escaping being condensed in the cooling-coil s. From Q Q the tar is forced by the pump r into the distillation apparatus, consisting of two rows of coils of cast-iron piping arranged in a furnace. The tar enters at the coolest part a, in the upper row of coils, and leaves at the hottest part Z in the lower row, about 460 mm. below a. The diameter of the pipe is larger at Z than at a, to allow for the expansion of the tar. The furnace is heated by means of liquid fuel or generator gas. The tar leaves the still at a temperature of about 300° C., and passes to the "pitch-scrubber" C, where it meets a current of superheated steam at a temperature of about 300° C., whereby all volatile products are expelled; the residual pitch flows from the bottom of the scrubber to the pitch-hole. The volatile products pass in succession first through the condensers T and H, cooled by the cold tar, as mentioned above, and then through the water-cooled coils g g. The anthracene oil is condensed in T, and the cresote oils in H, and in the condenser k surrounded by warm water; the condensed oils pass to the tanks M M and N N respectively. The light oils are condensed in g g and are collected in the tanks O O. It is stated that the condensing action of the tar in T and H can be so regulated, that products of constant sp. gr. can be obtained during several months. The whole system is worked under a vacuum of about 550 mm., and in order to avoid loss of volatile products, a water-tower w, and an oil-tower Oe are interposed between the vacuum-pump L and the condensers. Siphon-tubes pp are provided, by means of which samples can be taken without disturbing the vacuum. It is stated that the whole apparatus can be worked by one man.—A. S.

Dimethylantracenes; Three —, obtained by the Reaction of Methylene Chloride and Aluminium Chloride on Toluene. J. Lavaux. Comptes rend., 1904, 140, 44-45.

By the reaction of methylene chloride and aluminium chloride on toluene, the author has produced and isolated three dimethylantracenes. As their constitution is not yet determined, he provisionally designates them A, B and C. Their respective melting-points are 240°, 244.5 and 86° C. In applying Friedel and Crafts' reaction, the yield is greatly increased if the temperature be so regulated as to be always just below that at which a rapid evolution of hydrochloric acid gas occurs; the gas should, in fact, be evolved only on agitation, and this agitation should be almost continuous. Another point is, that instead of distilling the whole of the mass obtained by treating the product of the reaction with water, it is better to separate any solid substance by decantation and filtration with the pump, recovering by distillation only the small amount dissolved in the water.—J. T. D.

Dibromoanthracene tetrabromide. P. Kaufler and M. Imhoff. Ber., 1904, 37, 4706-4709.

On heating dibromoanthracene tetrabromide to 200° C. until the liberation of bromine and hydrogen bromide ceases, and crystallising the product from hot benzene, the authors obtained tetrabromoanthracene melting at 298-300° C., whilst from the mother liquor tribromoanthracene melting at 171° C. was separated. On oxidation, dibromoanthraquinone (m. pt. 289°-290° C.) was obtained from the tetrabromo derivative and bromoanthraquinone (m. pt. 201°-202° C.) from the tribromo compound. Experiments made to establish the constitution of the new dibromoanthraquinone have shown it to be identical with 2,6-dibromoanthraquinone obtained by the bromination of 2,6-diaminoanthraquinone.—D. B.

Petroleum Residues [Mazut]; Possibility of Ascertaining Yield and Quality of Lubricating Oils from the Quality

of —, K. Charitschkow. Westnik shirok.veshtsch., 1904, 5, 150; Chem.-Zeit., 1904, 28, Rep., 392.

Grosny petroleum residue is deeper in colour and more viscous than that from Baku oil, the viscosity (at 50° C. being 12.5:5.2, and belongs to the group ("Koskasi") arranged by the author, and comprising residues which are easily decolorised by sulphuric acid as a consequence of the decomposition of their resinous constituents. The solution in benzene, when treated with sulphuric acid, clarifies and exhibits dichroism. To determine whether any definite connection exists between the high density and viscosity of these residues and their high percentage of resins, the author employed a method of hot purification, the usual methods of eliminating the resins being difficult of application. The residue is heated to 70-80° C., and is treated with small successive portions of sulphuric acid until the resin-free hydrocarbons have a greenish colour, the viscous black deposit of resins being easily removed. Provided no acid reaction products are present, the purified oil does not emulsify in the subsequent alkali treatment and washing. A sample of residue, treated in this way, had the sp. gr. 0.944 at 15° C., and the viscosity (Engler) 14' 20" at 50° C. After treatment with 30 per cent. of sulphuric acid, the product consisted of 67.5 per cent. of acid resin ("goudron") and 60 per cent. of a greenish brown oil of sp. gr. 0.912 at 15° C., and the viscosity 5' 15" at 50° C. This shows that the residue from Grosny petroleum is similar, when refined, to that from Baku oil, and that its specific properties are due to the large proportion of contained resins. When freed from the "solar oil" fractions, the oil has about the same viscosity as engine oil. By means of the method specified it is possible to ascertain the suitability of a residue for the production of lubricating oils, but the resulting oils will need to be rectified by steam or *in vacuo*. It is also applicable to the refining of highly viscous oils and where the acid residue is intended as an asphaltum substitute.—C. S.

Wood-Tar Pitch; Behaviour of —, with certain Organic Solvents. B. M. Margosches. XXIII., page 107.

ENGLISH PATENTS.

Hydrocyanic Acid and Cyanides; Manufacture of — (from Gas Liquor). G. E. Davis. Eng. Pat. 3018, Feb. 6, 1904. VII., page 90.

Sulphate of Ammonia Saturators. K. Zimpell, Stettin, Germany. Eng. Pat. 23,379, Oct. 29, 1904. Under Internat. Conv., March 30, 1904.

IMPROVEMENTS are claimed in the saturator described in Eng. Pat. 6891 of 1904 (this J., 1904, 660). In the saturator tank is suspended a bell, the top of which forms the base of the auxiliary saturator tank; this latter is open at the top, and has a short central pipe extending upwards from its base, and connecting it with the bell. This pipe is covered by a small bell, the lower edge of which is serrated, and which passes below the acid level of the auxiliary saturator tank; this bell is fixed to the vertical pipe which conveys the ammoniacal gases to the main saturator. A third bell covers the former (small) bell, and is likewise fixed to the vertical pipe; it is provided with a gas outlet and an acid funnel, and extends to the bottom of the auxiliary saturator, openings being provided near the base, so that the acid within and without the bell may maintain the same composition, thus allowing the progress of the reaction to be easily examined, and also ensuring a continuous and regular overflow of acid through the pipe which is provided in the side of the auxiliary saturator.—T. F. B.

IV.—COLOURING MATTERS AND DYE STUFFS.

Ammonium Nitrite (or nascent Nitrogen) and Ammonium Nitrate (or nascent Nitrous Oxide); Reaction of —, on Aromatic Compounds. W. Vaucl. Chem.-Zeit., 1904, 28, 1245-1246.

When to an aqueous solution of a mixture of sodium nitrate and ammonium chloride at 60–70° C. are added various aromatic compounds, the final result of the reactions occurring depends on the particular compound used; but the initial stage seems to be in all cases the formation of a nitroso-compound by substitution of NO for a hydrogen atom.

Aniline forms besides aminoazobenzene, other decomposition products, but no diazo-compounds could be recognised as intermediate products.

S-diam raphthionate: A dyestuff is formed with the formula:

Dimethylaniline and the phenols yield nitroso-compounds.

Pyrogallol absorbs nitrous oxide gas though without losing its power of absorbing oxygen—a fact of importance in gas-analysis.—J. T. D.

Dibromo-1,5-diaminoanthraquinone: Constitution of —. R. Scholl and A. Krieger. Ber. 1904 37 4684–4686.

CRUDE dibromo-1,5-diaminoanthraquinone was converted by means of cold nitric acid of sp. gr. 1.50–1.52 into the corresponding dinitrodinitramine. By treatment with alcoholic hydrochloric acid the admixed nitrated nitramine from unbrominated diaminoanthraquinone was converted into the diamino compound, which was separated from the brominated nitramines by its insolubility in ammonia solution, in which the latter were dissolved. On standing, the ammonium salt of 4,8-dinitro-2,6-dibromo-1,5-dinitraminoanthraquinone separated out leaving a similar tetrabrominated compound in solution. It was "denitrated" by the action of phenol in sulphuric acid, forming 2,6-dibromo-4,8-dinitro-1,5-diaminoanthraquinone, which on reduction with potassium sulphide yielded 2,6-dibromo-1,4,5,8-tetraminoanthraquinone. The same substance is obtained directly from 2,6-dibromo-4,8-dinitro-1,5-dinitraminoanthraquinone by reducing the ammonium salt by means of hot aqueous hydrogen sulphide or by phenylhydrazine. The product forms blue crystals with a bronzy lustre very similar in appearance to indigo; it is almost insoluble in ordinary solvents, which can be crystallised from aniline or quinoline. As it does not react with phenanthrene, the constitution given is deduced by the authors, from which it follows that the product from which they start is 2,6-dibromo-1,5-diaminoanthraquinone. Cotton fabrics are dyed in pure indigo shades by immersion in a solution of the ammonium salt of 2,6-dibromo-1,5-dinitramino-4,8-dinitroanthraquinone and subsequent exposure to an atmosphere of hydrogen sulphide, 2,6-dibromo-1,4,5,8-tetraminoanthraquinone being formed on the fibre.

—E. F.

2,6-Dibromo-4,8-dinitro-1,5-dinitraminoanthraquinone: Behaviour of the Nitramine Group during the action of Aromatic Bases on —. R. Scholl and A. Krieger. Ber., 1904, 37, 4686–4692.

On boiling 2,6-dibromo-4,8-dinitro-1,5-dinitraminoanthraquinone with aniline for some hours and cooling, crystals of azophenine and of a blue dyestuff separate out. The latter is more soluble in nitrobenzene than azophenine, and hence they can easily be separated. After removing small quantities of a green dyestuff by washing with benzene, the product was recrystallised from nitrobenzene. It was found to be 2,6-dibromo-1,5-diamino-4,8-dianilidoanthraquinone. With 100 per cent. sulphuric acid at 40° C. it forms a sulphonic acid, soluble in water, which dyes wool in fast, greenish-blue shades. On warming 2,6-dibromo-4,8-dinitro-1,5-dinitraminoanthraquinone to 100° C. with aniline for half an hour, a green solution is obtained, from which a green dyestuff and aminoazobenzene can be separated. The green dyestuff has the composition $\text{C}_{38}\text{H}_{26}\text{O}_2\text{N}_8\text{Br}_2$ and is probably 2,6-dibromo-4,8-dianilidoanthraquinone-1,5-bisazoanilide

stuff, differing from the blue dyestuff obtained with boiling aniline by being very soluble in cold aniline. By the action of boiling *p*-toluidine on 2,6-dibromo-4,8-dinitro-1,5-dinitraminoanthraquinone a blue dyestuff is obtained which is 2,6-dibromo-1,5-diamino-4,8-di-*p*-toluidinoanthraquinone. Dimethyl-aniline reacts with the free nitramine with formation of so much heat that the nitramine may explode, but if the ammonium salt is used the reaction is quite quiet. The product, which is 2,6-dibromo-4,8-dinitroanthraquinone-1,5-bisazoxydimethylaniline is a blue-black, finely crystalline substance which can be crystallised from boiling quinoline. Its solutions are blue. On heating alone, or more smoothly in nitrobenzene solution, it forms 2,6-dibromo-4,8-dinitro-1,5-diaminoanthraquinone.—E. F.

p-Diphenylbismethylmethane: Nitro Derivatives of —. T. Szeky. Ber. d. med.-naturw. Sektion d. siebenbürg. Museumvereins, 1901, 1–13. Chem. Centr., 1904, 2, 1737.

DINITRO-*p*-DIPHENYLBISMETHYLMETHANE, when reduced with tin and hydrochloric acid, gives the corresponding diamino compound, $(\text{CH}_3)_2\text{C}(\text{C}_6\text{H}_3(\text{OH})(\text{NH}_2))_2$. When the solution of the diazochloride of this diamine is poured into an alkaline β -naphthol solution, the sodium salt of *p*-diphenylbismethylmethanebisazido- β -naphthol, $(\text{CH}_3)_2\text{C}(\text{C}_6\text{H}_3(\text{OH})\text{N}:\text{N}:\text{C}_{10}\text{H}_6(\text{OH}))_2$, is formed as a dark blue amorphous substance. The dyestuff has a green reflex resembling that of Magenta; it dissolves in alcohol with a red colour and dyes silk a brilliant red.—A. S.

Diazo-Reaction in the Diphenyl Series: The —. H. Ethoxybenzidine. J. C. Cain. Chem. Soc. Proc., 1904, 20, 249.

If the solution of the diazonium salt prepared from ethoxybenzidine be heated, one diazonium group is replaced by hydroxyl as usual, but the other remains intact. The diazonium group adjacent to the ethoxy group appears to be the one not acted upon, since the diazonium salt of dianisidine when subjected to similar treatment is much more stable than that of benzidine. The hydroxy-diazonium sulphate can be recrystallised from boiling dilute sulphuric acid; it forms long, acicular, brown crystals, easily soluble in water, and having the composition $(\text{OH})\text{C}_6\text{H}_4\text{C}_6\text{H}_3(\text{OC}_2\text{H}_5)\text{N}(\text{N})\text{HSO}_4$. The free diazonium hydroxide is precipitated by sodium carbonate as a lilac-coloured mass, which dissolves in acids forming the corresponding salts.—A. S.

Aminoazo Compounds: Method for the Direct Production of Certain —. R. Meldola and L. Eynon. Chem. Soc. Proc., 1904, 20, 250–251.

If a strong solution of sodium bichromate be added to aqueous solutions of diazotised amines, in most cases a crystalline precipitate of the diazonium chromate is produced, which can be isolated and used in the solid condition. The application of this reaction to diamines allows of the direct production of aminoazo compounds. For example, diazotised *p*-phenylenediamine gives a chromate of the composition, $\text{NH}_2\text{C}_6\text{H}_4\text{N}_2\text{HCrO}_4$, which combines directly with phenols and amines to form aminoazo compounds. The authors have prepared *p*-aminobenzenazo- β -naphthol by this method. *p*-Aminophenol forms a normal diazonium bichromate, $(\text{HO}\text{C}_6\text{H}_4\text{N}_2)_2\text{Cr}_2\text{O}_7$. The solid diazonium chromates are all more or less explosive when dry, and some of them may be capable of technical application. In discussion, the author stated that he had not been able to isolate chromates of the tetrazo derivatives of simple diamines.—A. S.

Resazurin: Three Isomeric Hydroxyl-Homologues of —. C. Bülow and C. Sautermeister. Ber., 1904, 37, 4715–4723.

EQUIMOLECULAR proportions of 2,4-diethoxybenzoyl-acetone and phloroglucinol were condensed by means of dry gaseous hydrochloric acid in glacial acetic acid solution. The product forms orange-red needles and is the hydrochloride of 2,2'(4'-diethoxyphenyl)-4-anhydromethyl-5,7-dihydroxy[1,4-benzopyranol]:

From pyrogallol and 2,4-diethoxybenzoylacetone 2-[2',4'-diethoxyphenyl]-4-anhydromethyl-7,8-dihydroxy-1,4-benzopyranol] was obtained, as a hydrochloride, in the same manner. This substance forms dark-red needles. It can be converted into the base by sodium acetate. The base dissolves in alcohol to a bluish-violet liquid. The product possesses all the properties of a true mordant dyestuff. On chrome-mordant it gives olive-green shades, which would compete with Coerulein, being equally fast as regards bleeding on to white, but it is not so fast as the latter to boiling acids, changing its shade and bleeding on to white under this treatment. The alumina lake shows similar properties. Both alumina and chrome lakes are decidedly duller, greyer and more yellow than those obtained from Coerulein-A paste, and could therefore not compete with the latter. The dyeing properties of the corresponding compound from resorcinol are also described. It gives similar shades to Alizarin Brown, fairly fast to alkali, but bleeding much more than the latter on to white.

Hydroxyhydroquinone and 2,4-diethoxybenzoylacetone condense in presence of hydrochloric acid in acetic acid solution to form the hydrochloride of 2-[2',4'-diethoxyphenyl]-4-anhydromethyl-6,7-dihydroxy-1,4-benzopyranol]. This forms golden yellow crystals. The base dissolves in organic solvents with yellowish-red colour.—E. F.

Crystal Violet: Action of Benzyl-magnesium Chloride on —. M. Freund and H. Beck. Ber., 1904, 37, 4679–4680.

The reaction was carried out in solution in dry ether. Only one molecular proportion of benzyl-magnesium chloride reacts, forming hexamethyltriaminotriphenylbenzylmethane $[(\text{CH}_3)_2\text{N} \cdot \text{C}_6\text{H}_4)_3\text{C} \cdot \text{CH}_2 \cdot \text{C}_6\text{H}_5$. The product forms grey crystals and yields no dyestuff with oxidising agents.—E. F.

Sulphide Dyestuffs; Existence and Function of Mercaptan Groups in Direct —. R. Vidal. Monit. Scient., 1905, 19, 25–27.

The solubility of "direct" sulphide dyestuffs in alkali sulphide solutions has been attributed to the presence of mercaptan groups. That this is not the correct view is shown by the fact that, when *p*-aminophenol is heated with a quantity of sulphur just sufficient for the formation of the thiazine groups, a product is obtained which is soluble in alkali sulphides, the solutions dyeing blue-black to blue shades; when this product is heated with alkali sulphide to a high temperature, a greenish dyestuff is obtained, identical with that produced on heating *p*-aminophenol with sulphur and alkali sulphide; oxidation of this greenish dyestuff reconverts it into the blue-black or blue dyestuff, whence it would appear that the mercaptan group had only the effect of modifying the shade of the dyestuff. By a comparison of the three black dyestuffs obtained by heating mono-, di-, and tri-aminohydroxydiphenylamine with sulphur, it is found that the more mercaptan groups are introduced (by heating with alkali sulphide), the greener will be the resulting dyestuff. It is also found that any reagent which will remove the mercaptan group will convert the greenish dyestuffs into the bluish ones. In the case of dyestuffs obtained from diphenylamine derivatives (or their equivalents) and sulphur alone, with the exception of those in which some highly basic grouping necessitates the presence of a mercaptan group to render them soluble in alkali sulphide, those dyestuffs containing hydroxy groups are all directly soluble, the solubility depending on the number of hydroxy groups present. It thus follows that the mercaptan groups are not essential for sulphide dyestuffs, and that their introduction is due to the action of alkali sulphide at high temperatures. It is said to be erroneous to attribute variations of shade to different substituents in the primary compounds. With regard to the mechanism of the formation of sulphide dyestuffs, the following reactions are considered to

represent it in the case of that obtained from *p*-aminophenol:—

—T. F. B.

SEE Eng. Pat. 26,372 of 1903; this J., 1903, 1289. — E. F. B.

Hydroxyalkylanilines; Process of making — W. Behagel and G. C. Schumann, Assignors to Badische Anilin und Soda-Fabrik, Ludwigshafen-on-Rhine, Germany. U.S. Pat. 778,772, Dec. 27, 1904.

HYDROXYALKYLANILINES are obtained by heating a glycolaldehyd with an aromatic amine in presence of water. A substance capable of neutralising mineral acids, such as sodium acetate, may also be added. The application of the process to the production of hydroxyethylaniline from glycolchlorhydrin and aniline is specially claimed. —E. F.

β-naphthol Dye [*Azo Dye-stuffs*] and *Process of making same*. K. Elbel, Assignor to Kalle and Co., Biebrich, Germany. U.S. Pat. 778,476, Dec. 27, 1904.

DI-AZO-DERIVATIVES of 1,2-aminonaphthol-sulphonic acids, such as 1,2-aminonaphthol-3,6-disulphonic acid are combined with β-naphthol in highly concentrated solutions and in presence of an excess of alkali. The products dye wool directly from a bath acidified with sulphuric acid in bluish-red to violet shades, convertible into violet to blue-blacks on subsequent treatment with bichromates. The product obtained with 1,2-aminonaphthol-3,6-disulphonic acid dyes wool in Bordeaux red shades which change to bright bluish-black on chroming. —E. F.

Monochloro-α-naphthol and Process of making same. K. Elbel, Assignor to Kalle and Co., Biebrich, Germany. U.S. Pat. 778,477, Dec. 27, 1904.

MONOCHLORO-α-NAPHTHOL is made by acting on solutions of alkali salts of α-naphthol with hypochlorites in molecular proportion, and subsequently acidifying the reaction product. It consists of white crystals, melting at 64.5°C., having a pungent smell and readily soluble in benzene, alcohol and ether. —E. F.

Sulphur Dye [*Sulphide Dye-stuffs*]; *Blue* —, and *Process of Making same*. K. Elbel, Assignor to Kalle and Co., Biebrich, Germany. U.S. Pat. 778,478, Dec. 27, 1904.

THE indophenols or phenyl-naphthylamine derivatives obtained by simultaneous oxidation of monochloro-α-naphthol and of a *p*-diamine of the benzene series are heated with alkali polysulphides. For instance, monochloro-α-naphthol is oxidised together with dimethyl-*p*-phenylenediamine, and the product is heated with alkali polysulphide either directly or after transforming it into the colourless phenyl-naphthylamine derivative. The products are easily soluble in aqueous sodium sulphide solution and dye un mordanted cotton from such solutions in violet to greenish-blue shades. The product obtained from dimethyl-*p*-phenylenediamine dyes in fast greenish-indigo shades. —E. F.

Ortho-dioxyanthraquinone Sulpho Acid, and Process of Making same [*Anthracene Dye-stuff*]. M. Hjnsky, Krefeld, Germany. U.S. Pat. 778,670, Dec. 27, 1904.

SEE Fr. Pat. 336,938 of 1903; this J., 1904, 438. —T. F. B.

FRENCH PATENTS.

Mono-azo Mordant Dye-stuffs. [*Azo Dye-stuffs*]; *Preparation of* —, Kalle and Co. Fr. Pat. 346,005, Sept. 2, 1904.

AMINO-*p*-CRESOL sulphonic acid [$\text{CH}_3 : \text{NH}_2 : \text{OH} : \text{SO}_3\text{H} = 1 : 3 : 4 : 5$] is acetylated, nitrated and saponified. The resulting nitro-amino-*p*-cresolsulphonic acid is diazotised and combined with β-naphthol. The dyestuff so obtained dyes wool from an acid bath in reddish-orange shades, which are transformed on subsequent treatment with chromium salts into violet-black shades which are extremely fast. If *p*-toluidine-*o*-sulphonic acid is acetylated and then nitrated, a nitro-acetyl-*p*-toluidine-*o*-sulphonic acid is obtained. When this is boiled with dilute alkalis it is converted into a nitro-*p*-cresolsulphonic acid, the acetyl-amino group being replaced by a hydroxyl group. This is reduced by means of zinc dust to the corresponding amino-compound and then nitrated, thus forming a nitro-amino-*p*-cresolsulphonic acid. On diazotisation and combination with β-naphthol this forms a dyestuff which dyes wool in violet shades which on subsequent chroming turn to a rather bluish violet-black which is said to be absolutely fast. —E. F.

Mono-azo Dye-stuffs [*Azo Dye-stuffs*], especially suitable for the *Manufacture of Lakes*; *Production of Orange* —, Badische Anilin- und Soda-Fabrik. Fr. Pat. 346,007, Sept. 2, 1904.

3,4-DICHLORO-1-NITROBENZENE is treated with fuming sulphuric acid and the sulphonic acid so formed is reduced with iron and acetic acid. The resulting compound is probably 3,4-dichloroaniline-5-sulphonic acid. 3,4-Dichloro-aniline-6-sulphonic acid is obtained either by sulphonating 3,4-dichloro-aniline with fuming sulphuric acid or by nitrating and subsequently reducing 3,4-dichlorobenzene-1-sulphonic acid. The dyestuffs are obtained by diazotising 3,4-dichloro-aniline-5-or-6-sulphonic acid and combining with β-naphthol. They are very insoluble, and form lakes which are said to be very fast to water and to lime and perfectly fast to light. —E. F.

Mono-azo Dye-stuff [*Azo Dye-stuffs*], especially suitable for the *Manufacture of Lakes*; *Production of Red* —, Badische Anilin- und Soda-Fabrik. Fr. Pat. 346,008, Sept. 2, 1904.

3,4-DICHLOROANILINE is diazotised and combined with β-naphtholdisulphonic acid R. The dyestuff forms lake which are said to be distinguished by slight solubility in water, brilliancy, and exceptional fastness to light. —E. F.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

Flax; Water-Retting of —, K. Störmer. Centr.-Bl. f. Bakter. u. Parasitenk., 1904, 13, 35–45, 171–185, 306–326. Chem. Centr., 1905, 1, 41.

THE water-retting of flax is a biological process induced by the action of debilitate organisms, the chief of which is an anaerobic *Plectridium*, which, in the absence of air ferments the pectin substances of the cellular material uniting the parenchymatous tissues, and thus causes loosening of the bast fibres. The absolute exclusion of oxygen, which is necessary in order that the fermentation may be set up, is brought about by numerous oxygen consuming bacteria and fungi. The products formed by the fermentation of the pectin substances are hydrogen and carbon dioxide, and organic acids, especially acetic and butyric acid and small quantities of valeric and lactic acids. The injurious action of the acids produced especially butyric acid, may be considerably diminished by adding alkali or lime to the retting liquid. It is advantageous to inoculate the liquid at the beginning of the retting with pure cultures of the anaerobic *Plectridium*. (See also this J., 1900, 143; 1904, 249.) —A. S.

Dyeing, Economics in —, E. Harter. *Färber-Zeit.*, 1905, 15, 3-4.

THE soap baths from dyeworks are collected in suitable vessels and heated by direct steam to from 75° to 90° C. Milk of lime is then added, from 15 to 20 kilos, of lime being required for 1 cbm. of soap water. The precipitate is collected in filter-presses, dried, and used for making illuminating gas.—D. B.

Fastness to Perspiration of Dyed Goods. E. Davelli. *Färber-Zeit.*, 1904, 15, 373-377.

THE usual method of testing the fastness of a colour to perspiration by means of acetic acid is quite unsuitable, as copious perspiration has usually an alkaline reaction. The following is a good test.

Make a solution containing 5 grms. of Marseilles soap and 3 c.c. of ammonia in one litre of water, and soak the pattern to be tested for ten minutes in this. Squeeze well, wrap the pattern tightly round a glass rod with a piece of calico, and leave at about 50° C. until quite dry. The amount of "bleeding" is a good measure of the fastness to perspiration.

In dyeing with acid dyestuffs, the fastness is improved by increasing the amount of acid added to the bath. As sulphuric acid tenders any cotton present, it can be replaced with great advantage by formic acid when dyeing mixed goods.—A. B. S.

ENGLISH PATENTS.

Oxidation Black on Animal Fibres, Mixtures of Animal and Vegetable Fibres, and Fabrics made from the same. Production of —, F. Köntzer, Zittau, Saxony. Eng. Pat. 21,634, Oct. 8, 1904.

COTTON and wool unions and all-wool fabrics can be satisfactorily dyed with aniline black by the ageing and after-chrome method, provided the material be treated, either before or after the oxidation, with some cyanogen compound, such as Prussian blue.—F. D. T.

Discharging Dyeings; Means for —, R. B. Ransford, Upper Norwood. From L. Cassella and Co., Frankfort-on-Maine, Germany. Eng. Pat. 2573, Feb. 2, 1904.

It is found that perfect discharges, even on dyed wool, can be obtained with formaldehyde-hydrosulphite mixed with a metallic oxide or carbonate, such as zinc oxide or magnesium carbonate. For example, the wool is printed with a mixture of zinc oxide, 250 parts; formaldehyde-hydrosulphite, 300 parts; gum mucilage, 350 parts; water, 100 parts; dried, steamed for 15 minutes, "soured" and rinsed.—T. F. B.

Waterproofed Textile Fabrics and other Materials, and the Method and Means Employed in Waterproofing them. G. Murray, Glasgow. Eng. Pat. 1930, Jan. 26, 1904.

FABRICS, paper, and other materials are waterproofed by first immersing them in hot linsed oil, and raising the oil to about its boiling point. The material is then dried

and treated with turpentine to soften it and prevent the formation of a hard skin, and finally coated with a suitable varnish, and dusted with powdered chalk or similar substance. Two or more sheets waterproofed in above manner may be fastened together by pressure. This process is adapted to be particularly applicable to waterproofing rope, &c., and for the production of roofing materials. —T. F. B.

Calendar Rolls or Rollers for Finishing Textile Goods, Paper and other Fabrics; Manufacture of —, J. Hübner and W. J. Pope, Manchester. Eng. Pat. 2758, Feb. 1, 1904.

Loose cotton or paper, previously treated by immersion in a mercerising or shrinking agent, e.g., caustic soda lye of 55° Tw., is compressed around the roller shaft, whereby the roller acquires greater superficial elasticity and wearing power.—F. D. T.

FRENCH PATENTS.

Artificial Silk; Treating Cellulose for the Manufacture of —, J. Foltzer. Fr. Pat. 345,687, July 15, 1904.

CELLULOSE, e.g., wood or cotton, is boiled under pressure with a solution of sodium carbonate and caustic soda. The product, which, to be properly acted upon by the solvent, should contain at least 12-15 per cent. of moisture, dissolves, it is claimed, at the ordinary temperature and in less than 24 hours' time, to the extent of 8-10 per cent. in a "direct" solvent.—E. B.

Wool Washing Machine. F. Bernhardt. Fr. Pat. 345,718, June 9, 1904.

RAW wool, in the loose state, is conveyed along the perforated bottom of a continuous washing machine (see figure) by means of forks 4, fixed at regular intervals in two parallel, endless chains 3, running during part of their course between guide frames 6. During its passage through the machine it is treated, on the counter current principle, with solutions of the potash salts, &c., extracted from the wool, contained in the several compartments

13-18 of a tank underneath the machine, which are pumped upon the wool and then return to the compartments whence they have been drawn, and which pass through overflow pipes or chambers from one compartment to another. Clean water is supplied at the exit end of the machine from a pipe 10, which delivers it between two pairs of squeezing rollers 8, 9, upon the wool as it is withdrawn from the machine, in amount regulated by an automatic float 11, to the end that the solution of the potash salts, &c., as it leaves the tank, shall be sufficiently concentrated to render its evaporation profitable.—E. B.

Silk and other Fibres: Process and Apparatus for the Conditioning of —, Soc. Anon. Co-operativa per la Stagionatura E l'Assaggio Delle Sete ed Aluni. Fr. Pat. 345,757, Aug. 22, 1904.

THE silk or other fibre is placed in a basket, which rests in a wide pipe, arranged over the air-inlet pipe of the conditioning apparatus, so that the hot air is made to pass directly through the fabrics, instead of, as is usually the case, merely passing over their surface.—F. D. T.

Dyeing Machine for Yarns in the form of Hanks. P. Aubry. Fr. Pat. 315,668, Aug. 18, 1904.

THE mechanism in question is mounted upon a framework composed of four uprights A (see figures) connected together by cross-stays, above and between two dye-vessels or two rows of dye-vessels, and consists essentially of shafting and gearing for rotating two series of reels 3, two drums 20 for supporting, or when required, winding

or unwinding chains from which a platform B, carrying the reels, is suspended, and apparatus for automatically arresting the platform as it is being raised or lowered and for rotating the reels. Motive power is supplied from an engine by a strap stretched upon a pulley 5 upon a shaft 4, and is conveyed from this, by means of a double coupling 6, to one or other of two pinion wheels which engage with a pinion wheel upon a vertical shaft 9, and cause this to turn either in the one or the opposite direction. This shaft by means of a clutch 10, can be made to turn either an endless screw 11 or a vertical shaft 12. Hanks being placed upon the reels, and the dye-vessels being filled with dye-liquors, the double coupling is brought by means of a handle 22 into gear with the wheel 7, and the endless screw is set in motion. The drums 15 and 20 which carry the chains supporting the platform are unwound, and the platform is thus caused to descend. As soon as the lower parts of the hanks are immersed in

FIG. 1.

FIG. 2.

the dye-baths, the clutch 10 is automatically moved by means of a rod 28, acting in connection with a lever 29, a rod 28A and mechanism attached to the coupling 6. The descent of the platform is thus arrested, and the reels are made to rotate. The handle 22 is next moved, to bring the wheel 8 into gear. The endless screw is then again brought into operation, and the drums are turned in the opposite direction to that in which they were previously revolved. The platform and the counterpoise are thus raised. When the platform reaches a certain height, the sleeve 26 upon the rod 28A comes into contact with a pin 30, and pushes upwards the rod, which, acting upon the coupling mechanism disengages the wheel 8, and automatically stops the machine. The hanks may then be removed and replaced.

A second claim relates to a method of dividing a dye-vessel into two or more parts by means of tightly fitting partitions, with the object of enabling a number of hanks to be simultaneously dyed in the same machine in as many different colours as there are separate compartments thus formed. To this end, flexible tubing is attached to the sides and bottom of the partitions, which are made to fit closely across the dye-vessel, against the sides and bottom. Water or a gas under pressure is then admitted through a valve 32 (Fig. 2), the excess being allowed to escape through a valve 33. A perfect joint is, it is stated, thus obtained.—E. B.

Textile Fabrics; Apparatus for the Dyeing, Cleaning, Bleaching, &c. of —. Soc. Obermaier. Fr. Pat. 345,945, Aug. 30, 1904.

THE liquors, with which the fabrics are to be treated, are made to circulate by means of the combined action of a slight pressure and a partial vacuum produced by an air-pump communicating with two closed tanks for holding the liquors. The machine described consists of a closed vessel for receiving the goods, communicating at the bottom and top with the liquor-tanks, in each of which is a float. A box arrangement with an inlet is placed under a false bottom in the dyeing vessel, and communicates with one of the liquor-tanks by means of a pipe whereby the liquor can enter the vessel under the false bottom. Another pipe connected with the second liquor-tank passes directly through the box having its outlet at the top of the dyeing vessel. The floats, above mentioned, interact with levers, placed in air-tight domes above the liquor tanks, which automatically work a specially constructed valve which alternately distributes the pressure and vacuum necessary for the proper circulation of the liquors.—F. D. T.

Metallic Pigments; New Composition for the Application of —, to Fabrics. L. Paul. Fr. Pat. 339,167, Nov. 13, 1903.

THE following mixture is recommended for printing fabrics:—Gelatin, 15 grms.; glycerin, 50 grms.; water, 835 grms.; metallic pigment, 100 grms.—F. D. T.

Hydrosulphites; Producing Discharges [Tissue Printing] by means of —. Soc. Badische Anilin- und Soda-Fabrik. Addition, dated Aug. 8, 1904 (date claimed under International Convention June 23, 1904), to Fr. Pat. 297,370 of Feb. 19, 1900.

THE process of discharging with printing mixtures prepared from solid hydrosulphite compounds, which forms the subject of the main patent, is not wholly successful, owing to the printing mixtures, especially when they contain soluble sodium or zinc salts, not keeping sufficiently well. This defect disappears, it is now found, when

an excess of caustic alkali is present in the mixtures. Discharge effects, which it has not been possible to produce hitherto, can be obtained with such mixtures. Thus a white discharge upon Naphthylamine Chloride is obtained by printing 40 parts of a mixture of 60 kilos. of hydrosulphite B.A.S.F. in powder (Fr. Pat. 341,718, this J., 1904, 900), 35 kilos. of glycerin, and 5 kilos. of caustic soda-lye at 10° B., admixed with 60 parts of an alkaline thickening prepared from 320 grms. of British gum, 320 c.c. of water, and 1 litre of caustic soda-lye at 15° B. A blue discharge may be produced by adding Indanthrene 8 to a similar mixture. The discharges are effected by steaming the printed tissues.—E. B.

Waterproof Compositions; Machine for Applying —, to Tissues. C. Lichtenstadt. Fr. Pat. 345,612, Aug. 16, 1904.

TISSUES are brought by means of a system of rollers into contact with strips of waterproofing composition, which are pressed upwards against one or both sides of them by adjustable mechanism, the ends of the strips overlapping the sides of the tissues being removed by a fluted roller. They are then passed between steam-heated cylinders to cause the composition to become more perfectly attached to or united with them.—E. B.

Drying Tissues after Washing, Dyeing or Finishing; Apparatus for —. G. Masurel-Leclercq. Fr. Pat. 345,281, Aug. 2, 1904.

TISSUES, which have been washed, dyed or passed through a finishing-mixture, are dried at full width and in a continuous manner, in a vertical hot-air chamber containing steam pipes, fans, and boards or plates, the last-named placed at an angle for the purpose of directing the ascending current of hot air upon the tissues. (See also Fr. Pat. 341,281; this J., 1904, 864.)—E. B.

VII.—ACIDS, ALKALIS, AND SALTS.

Nitric and Sulphuric Acids; Properties of Mixtures of —. A. Saposchnikow. Z. physik. Chem., 1904, 49, 697–708.

THE author has made determinations of the vapour pressure, sp. gr., and electric conductivity of mixtures of nitric and sulphuric acid. For the vapour pressure determinations, nitric acid of sp. gr. 1.5144 at 15° C., containing 98.95 per cent. of nitric acid monohydrate (HNO₃) and 0.88 per cent. of nitrogen peroxide, and sulphuric acid of sp. gr. 1.841 at 15° C., containing 98 per cent. of sulphuric acid monohydrate (H₂SO₄) were used. The results obtained are given in the following table:—

Percentage of Sulphuric Acid.	Vapour Pressure in mm. at 25° C.	Percentage of Sulphuric Acid.	Vapour Pressure in mm. at 25° C.
0.00	46.20	49.72	30.30
2.77	41.24	59.90	25.30
9.95	40.80	69.80	19.38
18.79	40.87	79.77	12.50
29.94	39.10	89.53	5.00
39.76	34.48		

For the determinations of sp. gr. and electric conductivity, nitric acid of sp. gr. 1.52, containing 94.85 per cent. of nitric acid monohydrate, 2.48 per cent. of oxides of nitrogen and 2.67 per cent. of water, and pure 100 per cent. sulphuric acid were used. The following results were obtained:—

Percentage of Sulphuric Acid.	Sp. Gr. at 25° 25° C.	Electric Conductivity at 25° C.	Percentage of Sulphuric Acid.	Sp. Gr. at 25° 25° C.	Electric Conductivity at 25° C.
0	1.5100	Mhos. 479.7·10 ⁻⁴	59.33	1.7898	714.5·10 ⁻⁴

(See also this J., 1904, 865, 935).—A. S

the amount of boric anhydride present increases) crystallises, and this portion has approximately the composition $\text{Na}_2\text{O} \cdot 6\text{B}_2\text{O}_3$. The results can be best explained by regarding the glass as a superfused, and therefore metastable form of the crystals. Mixtures containing 1 mol. or more of boric anhydride per mol. of sodium oxide probably consist of a borate of approximately the composition $\text{Na}_2\text{O} \cdot 5\text{B}_2\text{O}_3$, dissolved in boric anhydride. At some point between $\text{Na}_2\text{O} \cdot 6\text{B}_2\text{O}_3$ and $\text{Na}_2\text{O} \cdot 4\text{B}_2\text{O}_3$, no free boric anhydride remains, and the whole mass will crystallise for the first time. With mixtures richer in sodium oxide, another borate of composition near $\text{Na}_2\text{O} \cdot 4\text{B}_2\text{O}_3$ begins to be formed, and homogeneous mixed crystals separate, the glass being merely the super-fused form of the solid solution.

For the analysis of the mixtures, a weighed quantity of the substance in very fine powder was treated with strong hydrochloric acid, and the solution evaporated to dryness, these operations being repeated, to convert the whole of the sodium into chloride. The residue was then repeatedly treated with small quantities of methyl alcohol and the mixture evaporated to dryness, whereby hydrochloric acid and boric acid were removed. The sodium chloride remaining was dissolved in water and determined by titration with $\text{N}/10$ silver nitrate solution.—A. S.

Hydrosulphites; Formation of —. M. Prad'homme, Rev. Gén. Mat. Col., 1905, 9, 1–2.

By the action of sulphur dioxide on sodium hydride, a white salt is obtained according to the following equation:—

On crystallisation from a little water two kinds of crystals are obtained. The aqueous solution, acidified with a few drops of hydrochloric acid, reduces silver nitrate and ammoniacal copper solutions similarly to the alkali hydrosulphites. It is probable that the salt $\text{Na}_2\text{S}_2\text{O}_4$ is hydrolysed by water into a mixture of bihydrosulphite and bisulphite.

This would account for the two crystalline forms. The compound $\text{Na}_2\text{S}_2\text{O}_4$ is probably an intermediate product in the preparation of hydrosulphite, for if not, we could suppress one molecule of NaHSO_3 in the equation $2\text{NaHSO}_3 + \text{SO}_2 + \text{Zn} = \text{Na}_2\text{S}_2\text{O}_4 + \text{ZnSO}_3 + \text{H}_2\text{O}$, and use the equation

and so obtain the same yield of NaHSO_2 from half the amount of NaHSO_3 , which is not the actual case.—A. B. S.

Lead Acetate; Manufacture of —. C. Bauer, Chem. Zeit., 1905, 29, 1–5.

In order to avoid the loss of acetic acid consequent on the evaporation of large quantities of liquor, lead acetate should always be prepared with acid of 60 per cent. strength. The litharge should be of 99 per cent. purity, and free from iron and alumina. 3000 kilos. of 60 per cent. acetic acid are pumped into a covered wooden vat of about 5 cub. metres capacity. The vat is fitted with a wooden stirrer, a reflux condenser and a wooden hopper with feed-roll, a copper steam-coil is also provided. The litharge (3090 kilos.) is introduced in quantities of 100 kilos. at a time, which require 50–60 minutes for complete solution at a temperature not exceeding 65°C . When the whole of the litharge is dissolved, the liquor is made slightly acid and should have a density of $70^\circ\text{--}72^\circ\text{B}$. at 65°C ; it is pumped over into two covered wooden clearing vats, each of 5 cub. metres capacity and fitted with reflux condensers. These vats are previously partly filled with mother liquors from a previous crystallisation at a density of $35^\circ\text{--}37^\circ\text{B}$., so that the mixture has a density of about $50^\circ\text{--}52^\circ\text{B}$. Strips of lead are suspended in these clearing vats in order to precipitate any dissolved copper. Clarification is effected by standing for 6 hours at $60^\circ\text{--}63^\circ\text{C}$; the solution is then passed through a filter-press with wooden plates, whence it flows to the crystallising vessels. It remains in these for 7–10 days, after which the mother liquors are run off, the salt is drained in centrifugal machines and dried in a vacuum chamber

at 30°C . Solutions at 56°B . yield only small crystals; if large crystals be desired they must be deposited from concentrated solutions having a density of $70^\circ\text{--}72^\circ\text{B}$. The crystallising vessels have a capacity of 3.5 cub. metres; they are covered and well insulated, and each is provided with a steam coil. The solution is run at a temperature of 60°C . and is cooled at the rate of 5°C . in 24 hours; crystallisation requires about 14 days. All undissolved residues from the vat, drying frame, &c., are extracted with water; the resulting liquors are the only ones in the whole process which require to be evaporated.—J. E. B.

Sulphides of Manganese; Composition of the Four —. J. C. Olsen and W. S. Rapalje, J. Amer. Chem. Soc., 1904, 26, 1615–1622.

The authors find that three distinct modifications of manganese sulphide exist, two of which, the red and the green, are anhydrous, whilst the grey sulphide, which appears to have been overlooked by most investigators, contains a considerable amount of water. The ordinary pink or flesh-coloured sulphide is a mixture of varying proportions of the grey and red sulphides. The authors consider that the difference in colour between the red and green sulphides is due to a difference in molecular structure, and that the green modification is probably the more complex, since: (1) The pink or red sulphide is invariably first formed by precipitation, the green being a transformation product of one of these modifications. (2) The green sulphide is more distinctly crystalline and larger-grained, and also by far the most stable substance.—A. S.

Chromic Sulphate; Existence of a green Normal —. A. Colson, Comptes rend., 1905, 140, 12–14.

By reducing, at the freezing point of water, a solution of chromic acid by the exact quantity of sulphur dioxide necessary for the purpose, and evaporating and drying *in vacuo*, the author has obtained a green chromic sulphate of formula $\text{Cr}_2(\text{SO}_4)_3 \cdot 10\text{H}_2\text{O}$, to which he attributes the constitutional formula

The molecular weight was determined cryoscopically, and agrees with the molecular formula just given.

—J. T. D.

Aluminium; Double Silicides of —. W. Manchot and A. Kieser, Annalen, 1904, 337, 353–361.

A MIXTURE of metallic chromium or potassium bichromate, with potassium silicofluoride and metallic aluminium, heated to the highest temperature of a Perrot furnace, gives a regulus, which leaves, after successive treatment with hot hydrochloric acid and dilute solution of sodium hydroxide, a substance of formula Cr_2AlSi_4 . It forms brilliant hexagonal crystals, opaque, greyish-white, with metallic lustre; hardness above 5, density 4.7. It is unaffected by mineral acids, except hydrofluoric, which rapidly dissolves it—still more rapidly when mixed with nitric acid. Sodium hydroxide solution does not dissolve it, but the melted hydroxide does so rapidly. Melted sodium carbonate, chlorate, or bisulphate does not affect it. When heated in oxygen it is not attacked; heated chlorine attacks it rapidly, the other halogens less so. If in the original fusion the proportion of silicofluoride be increased, mixtures are obtained of Cr_2AlSi_3 and Cr_2AlSi_2 . This latter substance is harder and denser than the former, but the two are generally similar in their properties. At the temperature of its formation, the higher silicide tends to dissociate into the lower and silicon.

Similar double silicides have been obtained of aluminium with iron, cobalt, nickel, manganese, molybdenum and tungsten but the first four have not been satisfactorily isolated from the regulus containing them, and the others have not been accurately analysed. The tungsten compound has a density of 9.5, contains 12 per cent. of silicon and very little aluminium. Chemically, it resembles the chromium compound.—J. T. D.

Sulphur; Heat of Combustion of —. H. Girard, Comptes rend., 1904, 139, 1219–1221.

THE author has determined the heat of formation of

sulphur dioxide by burning sulphur in oxygen under pressure in the calorimetric bomb, determining at the same time the proportion of sulphur which is converted into sulphuric anhydride. The tabulated results show that the heat of formation of sulphur dioxide (gas) from sulphur (octahedral modification) increases with the pressure, the value for 2.5 atmospheres being 70.43 cal., and that for 45 atmospheres, 81.13 cal. The proportion of sulphur converted into sulphuric anhydride also increases with the pressure. The increase of the heat of formation of sulphur dioxide is strictly proportional to the increase of pressure up to 35 atmospheres, above which point the heat evolved increases more gradually. This increase in the heat of combustion is attributed to the production of increasing quantities of persulphuric anhydride as the pressure rises.—J. F. B.

Sulphuric Acid; Determination of —, by Benzidine Hydrochloride. Determination of Sulphur in Pyrites. G. von Knorre. XXIII., page 106.

Chlorine; Manufacture of —, by Electrolysing Sodium Chloride, and Apparatus therefor. S. Leatham, York, and E. G. P. Bousfield, Hendon, Middlesex. Eng. Pat. 456, Jan. 7, 1904.

That part of the cell where sodium hydroxide is produced is supplied with some compound of chlorine, such as hydrochloric acid, capable of reacting to reproduce sodium chloride. The compound may be introduced through a hollow and perforated cathode.—R. S. H.

UNITED STATES PATENTS.

Sulphur Trioxide; Process of Making —. H. S. Blackmore, Mount Vernon, N.Y. U.S. Pat. 778,099, Dec. 20, 1904.

SULPHUR dioxide, together with "a gaseous substance

capable of producing an endothermic reaction" therewith, is passed through a heated compartment, and the application of heat is so controlled that the temperature is kept below the dissociating point of sulphur trioxide, by "chemical refrigeration" in some cases. The sulphur trioxide thus produced is condensed, and the gaseous by-product is oxidised, mixed with more sulphur dioxide, and the process continued. One of the claims is for treating a mixture of sulphur dioxide with carbon dioxide in the manner described. Another of the claims is for "the process of making compounds of sulphur and oxygen which evolve heat on their formation" by "uniting substances forming the same, and simultaneously producing a substance capable of absorbing heat during its formation, and apportioning and disposing the ingredients so that the heat which would be evolved in the formation of one is absorbed by the other to such a degree that the generation of a temperature sufficient to dissociate the sulphur-oxygen compound is avoided." (Compare U.S. Pat. 724,251 of 1903; and U.S. Pat. 769,585 of 1904, this J., 1903, 554; and 1904, 936.)—E. S.

Pyrites; Apparatus for Treating —. W. B. Simons. Charleston, S.C. U.S. Pat. 778,149, Dec. 20, 1904.

IN a pyrites furnace, two or more rows of hollow bars horizontally arranged with spaces between, are superposed, each row being at a certain distance from the one next above or below, with a connected series of stirrers over each row, whereby the pyrites may be caused to descend while burning, from range to range.—E. S.

Ammonia and Caustic Alkali; Method of Production of —, by Electrolysis. G. E. Cassel. Fr. Pat. 346,060 Sept. 3, 1904. XI. A., page 95.

Copper, Zinc, Cadmium, Silver, Nickel, Cobalt, and Tungsten; Obtaining Hydroxides of —, in the Wet Way, by Direct Extraction. D. Lance. First Addition, dated Aug. 18, 1904, to Fr. Pat. 342,865, of May 4, 1904 (See this J., 1904, 1032).

IN attacking silicious nickel ores, nitrous sulphuric acid to which a decomposable chloride or concentrated sea water is added, is used, and the attacking acid is maintained at a stated density, by addition of water, and towards the end of the operation, of sodium bisulphate solution in order to hydrate the salts formed.

Plant for the manufacture of sulphuric acid by the chamber process is shown, but instead of the usual Glover tower, an apparatus of the "Alsing" type is provided in which the ore is agitated with nitrous sulphuric acid, chloride and sodium bisulphate resulting from the manufacture of nitric acid, the mixture being heated by injection of hot air, whilst the escaping nitrous gas are led back to the lead chambers. The function of the "Alsing" apparatus is stated to be wholly analogous to that of the Glover tower which it replaces, except that the sulphuric acid is discharged as sulphate of the metal dissolved. The nitrous and chloro-nitrous products are thus continuously regenerated. Instead of heating the "Alsing" apparatus by hot air, the sulphuric acid may be formed in the cylinders of the apparatus itself as in ordinary lead chambers, by passing in hot sulphur dioxide gas with the usual oxidising agents.—E. S.

VIII.—GLASS, POTTERY, AND ENAMELS.

Sodium Borates; Some Physical Characters of the — with a New and Rapid Method for the Determination of Melting Points. C. H. Burgess and A. Holt, Jr. VII., page 88.

ENGLISH PATENTS.

Glass; Apparatus for use in the Manufacture of Sheet and of other Articles, of —. E. Gobbe, Junr. Belgium. Eng. Pat. 2470, Feb. 1, 1904.

A CYLINDRICAL steel or cast-iron vessel to receive the

molten glass is provided with an opening at its lower end closed by a slide, and, at its upper end, with pipes and cocks for creating a vacuum in, or supplying compressed air to, the interior of the vessel. The vessel is filled with glass by exhausting it, whilst its lower end dips into the molten glass, and it is emptied by forcing compressed air into it. The parts of the vessel in contact with the glass may be water-cooled or protected by a refractory lining, which last may extend further downwards than the metal casing of the vessel. A sight tube may also be provided. In order to make sheet glass by means of this apparatus, the opening at the bottom is made in the form of a long narrow slot, through which the glass issues slowly, being at the same time rapidly cooled by air-jets on both sides. By making the vessel in two halves it may also be used as a mould for bottles, &c. In this case it is filled with glass as usual, and the glass forced out, leaving the water-cooled walls of the vessel covered with a layer of glass. The glass left in the lower opening is then finished into the bottom of the bottle by a tool introduced through the opening.

—A. G. L.

Glass Melting Furnaces. E. Baudoux, Genappe, Belgium. Eng. Pat. 19,067, Sept. 3, 1904.

A NUMBER of small "monolithic" tanks are set in a furnace divided by a wall with openings for the tanks into a larger melting and a smaller working compartment. By means of two transverse partitions, each tank is divided into a working, a refining, and a melting compartment. The arrangement enables different products to be produced continuously and simultaneously with only one furnace.

—A. G. L.

Filter-Presses [Potters' "Slip" Presses]; Trays for —. T. Lawrence, Colwyn Bay, Wales. Eng. Pat. 2211, Jan. 29, 1904.

THE claim is for a light rectangular tray for use with potters' slip presses, consisting of two sheets of galvanised wire gauze clamped to each side of a flat sheet of galvanised metal, and secured by means of oak rails and screws. The metal sheet is pierced by a circular hole at a suitable distance from one edge, and guide tubes are fixed at the side to support the trays upon the framework of the "slip" presses.—L. F. G.

Ceramic Printing and the like. R. Marzin, Eichwald, Austria. Eng. Pat. 1933, Jan. 26, 1904.

THE paste for ceramic printing processes is made by heating and working together the pulverised underglazing colour, such as cobalt blue, with a mixture of extract of aloe or other sticky plant substance, glycerin, syrup and an alkali carbonate. A small quantity of citric, tartaric, or similar acid may be advantageously added.—A. G. L.

UNITED STATES PATENTS.

Refractory Material [Fused Quartz]; Manipulation of—. E. Thomson, Assignor to General Electric Co. U.S. Pat. 778,286, Dec. 27, 1904. XI. A., page 95.

Vitreous Ware; Art of Decorating —. R. K. Duncan, Washington Pa. U.S. Pat. 772,876, Oct. 18, 1904.

To produce letters and designs on vitreous ware, a material called "lead sub-borate" is used. This is made by melting together, at a low red heat, either 111.5 parts of litharge, or 113.8 of red lead, or 165.5 of lead nitrate, together with 31 parts of crystallised, or 17.5 of fused, boric acid. If lead nitrate is used, a somewhat better colour is obtained than with the oxides of lead; a mixture of 17.5 parts of lead nitrate, 100 of litharge and 31 of crystallised boric acid may be used with advantage. The material forms an almost colourless mass, which, in the fused condition, readily dissolves colouring matters, such as metallic oxides. The material is rendered opaque by the addition of oxides of antimony, arsenic, tin, &c., or by very careful heating. The fused material is granulated in all cases by pouring it into water, and then powdered in an agate mortar, or between agate rollers. It is applied by means of stencil-plates to the articles as

these are taken, whilst barely red-hot, from the moulds. If the temperature of the articles at this stage, however, should be too high, the fusibility of the material must be diminished, which may be done either by increasing the proportion of boric acid used, or, preferably, by adding a substance such as baryta, to it, which raises its melting point. (See also U.S. Pat. 748,850, Jan. 5, 1904; this J., 1904, 116.)—A. G. L.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Portland Cement; Russian Standards for —. Riga Ind.-Zeit., 1904, 30, 189. Chem.-Zeit., 1904, 28, Rep. 391–392.

THE term "Portland Cement" shall apply to products obtained from natural marl or artificial mixtures of clay and calcium carbonate, kilned until sintering occurs, and then ground to the fineness of flour. The hydraulic modulus, i.e., ratio of lime and alkalis to silica, alumina and ferric oxide must not be less than 1.7, or more than 2.2, and the proportion of sulphur trioxide should not exceed 1.75 per cent., magnesia 3.0 per cent., and foreign substances 2.0 per cent.

Sampling.—In parcels of more than 3000 casks, a sample of 15 lb. shall be drawn for every ton in 0.3 per cent. of the total weight of each 3000 casks. Between 2000 and 1000 casks the latter figure shall form the basis of division, the samples being taken from 0.5 per cent. of the tonnage, whilst below 1000 casks, three casks shall be sampled; but if the parcel is less than 500 casks it need only be tested for sp. gr. and constancy of volume. All tests to be made at a temperature of 16°–18° C., all the materials being brought to this temperature; if this is impracticable, the report must be endorsed to that effect. Not more than six test samples to be prepared from the same cement paste, the blocks to be finished before hardening has commenced. The paste must be manipulated, without interruption, for 5 minutes after adding the water. The specific gravity is to be determined with the volumometer of Schumann or Le Chatelier-Candlot, and the sp. gr. of the paste dried at about 120° C. must not fall below 3.05.

Setting Test.—Hardening must not commence sooner than a quarter of an hour after the addition of the (pure, fresh) water, and must not be complete sooner than 1 hour or later than 12 hours. The test samples must be of normal consistence, this property being determined by mixing 400 grms. of the cement with sufficient water to make a stiff paste, and gently placing the latter in a small cylinder, 4 cm. high and 8 cm. wide, resting on a glass plate. A cylindrical shaft, 1 cm. in diameter and weighing 330 grms., is carefully lowered into the paste until the pointer on the attached scale is opposite the mark 40, and is then allowed to sink down by its own weight. The standard consistence corresponds to mark 5½–6½ on the scale, and is generally obtained by the use of 22–30 per cent. of water. The setting test is performed on quantities of 400 grms. of cement in the Vicat apparatus (load 300 grms.), at intervals of 5 minutes, the commencement of setting being indicated when the needle stops at ½ mm. from the bottom, and the end being reached when the needle does not penetrate deeper than ½ mm. below the surface. The preliminary tests can be performed on blocks 8–10 cm. in diameter and 1 cm. thick.

Constancy of Volume.—Cakes made from normal paste should not exhibit curvature or radial cracks at the edges when warmed, or when left in water for 27 days. In the hot test the cakes are placed, 24 hours after setting, in an air oven, and heated to 120° C. for at least 1½ hours.

Fineness.—The dry cement must not leave more than 50 per cent. of residue when passed through a sieve with 4900 meshes (of 0.05 mm. wire) per sq. cm., or more than 15 per cent. on a 900-mesh sieve of 0.1 mm. wire.

Tensile Strength.—The test blocks must be uniformly prepared from normal mortar, and have a sectional area of 5 sq. cm. at the point of rupture, the mean of the four highest values furnished by six blocks in the Michaldis' tester being taken as representing the breaking strain.

In the case of cement-sand mixtures, the amount of water necessary to produce normal consistence is determined with the rammer, or stated by the maker; otherwise, about 10 per cent. of the weight of the mixture is employed, until a workable paste is formed. This paste is rammed in the mould by the exercise of mechanical force represented by 1 kg. or 2.2 lbs. of dry substance, and under this treatment the block should exude a milky liquid. The weight of unit volume of the freshly made block is the strength of the normal mortar 1.36, and ramming must be continued until this weight coincides with the above-mentioned figure. With sample blocks of pure cement the test is similar in the mould, and the marble base is tapped against the table before stroking off the excess. The minimum tensile strength of these blocks is 25 kg. or 55 lbs. per sq. cm. at the end of the first 7 days, and 25 kg. or 55 lbs. after 28 days, but of the value at the first test a 25 per cent. increase and test need be made. The sand used for the compressed mixtures is quartz sand that has been passed through sieves with 60, 144 and 225 meshes respectively per sq. cm.; the residues left on the two latter being mixed in equal proportions and used as normal sand. The thickness of the wire in the three sieves shall be 0.4, 0.3 and 0.2 mm. respectively. The minimum tensile strength of the blocks shall be 7 kilos. per sq. cm. at the end of 7 days, and 10 lbs. after 28 days.

Portable Casks. Casks must have a uniform weight of 100 lb. nett, and about 110 lb. gross (110 lb. 36-lb.), and payment shall be made on the nett weight, without any allowance for leakage. The casks must be marked "Portland Cement," with the maker's name, a number indicating to which delivery it belongs, and the year of manufacture. Delivery in bags allowed only by consent. Loss by leakage not to exceed 2 per cent., unless otherwise agreed. 1 kilo, 1000 grms., = 2.2 lb.; 1 sq. cm. = 0.155 sq. in.; 1 cm. = 0.39 in.]—C. S.

ENGLISH PATENTS.

Cellular and Fibrous Substances: Treatment by Impregnation of Various Gases, and Apparatus for the Purpose. The Electric Timber-Seasoning and Preservation Co., Ltd., and J. H. West, London. Eng. Pat. 26,899, Dec. 8, 1903.

The material to be impregnated, such as wood, is almost completely immersed in a bath of the liquid with which it is to be charged, so that the uppermost surface is maintained practically parallel with the top surface of the bath. The upper and lower surfaces of the material bear upon metallic electrodes, from which a current traverses the body under treatment. A special form of tank suitable for the process is described. The upper electrode is provided with a pad of absorbent material which can be wetted for maintaining moist contact with the upper, unimmersed, surface of the material.—R. S. H.

Fire-proof Paint or Coating; Composition of Matter for —. W. Fairweather, Glasgow and London, from A. B. Nettleton, Chicago, Ill. Eng. Pat. 22,423, Oct. 18, 1904.

POWDERED silica or carbide is gradually added to an equal weight of semi-liquid water glass, preferably sodium, not potassium silicate. Unless the paint can be applied immediately after mixing, from 3 to 10 per cent. of calcium carbonate is also added to it, to prevent an efflorescence which otherwise takes place shortly after mixing.—A. G. L.

Kilns or Furnaces; Impts. in —, especially applicable to Kilns for Burning Lime, Cement or the like. B. Blount and R. E. Middleton, London. Eng. Pat. 26,778, Dec. 7, 1903.

The material to be burnt is continuously fed on to the bottom of a substantially annular kiln or furnace, which bottom is caused to travel on a circular track or itself forms part of a disc rotating on suitable bearings. Fuel is injected by one or more nozzles, preferably placed near the discharge end of the kiln, in a direction opposed to that of rotation. The burnt material is removed from the kiln before it has travelled through an angle of 360°.

—A. G. L.

Kiln for Burning Cement or Reducing or Calcining Ores. G. Gröndal, Djursholm, Sweden. Eng. Pat. 6635, March 18, 1904.

SEE Fr. Pat. 341,382 of 1904; this J., 1904, 867.—T. F. B.

Emery, Artificial; Manufacture of —. A. Gacon, Marly le Roi, France. Eng. Pat. 23,192, Oct. 31, 1904.

A MIXTURE is made under a jet of water of 769 kilos. of bauxite (preferably ferruginous), 513 kilos. of coke, 50 kilos. of sodium nitrate, and 250 kilos. of sawdust. The firm-pasty mass produced is suitably moulded, stacked in a furnace and fired, the product obtained being afterwards pulverised.—A. G. L.

UNITED STATES PATENTS.

Fire-Brick Composition. J. Anderson, Monaca, Pa. U.S. Pat. 777,995, Dec. 20, 1904.

THE composition consists of silica-sand 90 per cent., asbestos 5 per cent., and fireclay 5 per cent., and is mixed with a sufficient quantity of salt water.—B. N.

Kiln [for Lime, &c.]. R. Booth, London, and F. Crosland, Egremont, Cheshire. U.S. Pat. 777,936, Dec. 20, 1904.

X.—METALLURGY.

Iron Metallurgy; The Forsell's Process of —. Teknisk Tidskrift, 1904, 34, 88. Chem.-Zeit. 1904, 28, Rep. 394.

EXPERIMENTS were made on a large scale with this process at the Rendsburg works, the charge consisting of 40 tons of scrap iron (Martin material with 0.2 per cent. of carbon); 40 tons of Kragerö ore (containing 58.29 per cent. of tribasic calcium phosphate (26.7 per cent. of phosphoric acid), 8.48 per cent. of alumina, 1.16 per cent. of ferric oxide, 3.37 per cent. of chlorine, 1.86 per cent. of hygroscopic moisture and 26.48 per cent. of residue insoluble in acid; together with 40 tons of blast-furnace coke and a sufficiency of lime and quartz. The slags gave on analysis 6.61—17.23 per cent. of total phosphoric acid, and 2.92—6.89 per cent. of phosphoric acid soluble in citric acid, and were all on this account suitable as fertilisers. The characteristic feature of the process, however, is that it enables scrap ingot iron to be worked up into pig iron, which can then be reconverted into ingot iron.—C. S.

Iron Oxides; Influence of Water Vapour on the Reduction of —, by Oxides of Carbon. O. Boudouard, Comptes rend., 1905, 140, 40-42.

IN view of Gayley's results, when using a dry air blast in the manufacture of iron (this J., 1904, 1148), the author has made laboratory experiments on the effect of passing the gases from oxalic acid over ferric oxide, and also carbon monoxide over ferrous oxide, each series being carried out with the gas dry in one case, and saturated with moisture at the ordinary temperature in another. The results show that the reducing action of the gas is stronger when it is dry than when moist; but the difference, which is very marked when the temperature is 400°—500°C., lessens as the temperature rises, and practically vanishes at 1050°C. In the cooler regions of the furnace there will be more complete reduction of the oxide of iron by carbon monoxide when dry, and as the carbon dioxide formed has at this lower temperature less tendency to react on the coke and re-form carbon monoxide, there will be an economy of fuel. Near the tuyères, however, the water of the moist gas decomposes, forming hydrogen and oxygen, and we have no exact knowledge of the subsequent behaviour of this hydrogen, which, in presence of carbon dioxide, may regenerate the monoxide and water vapour.—J. T. D.

Steels; Brittleness of certain —. A. Perot and H. M. Lévy. Comptes rend., 1904, 139, 1198—1200.

THE authors have examined, by means of an apparatus designed by themselves, specimens of steel. They find very variable results for the brittleness under apparently identical conditions, and conclude that it varies at different parts of the steel. The brittleness varies, too, with the rapidity of the shock; for the same steel which suffers a considerable permanent deformation before breaking with a force slowly applied, breaks with much less previous deformation as the speed of shock is increased, and at a sufficient speed of shock is perfectly brittle, that is to say, suffers no permanent deformation before breaking. —J. T. D.

Calcium; Metallic —. Part I. K. Arndt. Ber., 1904, 37, 4733–4738.

THE author made a careful examination of the calcium which can now be obtained commercially. The usual impurities are silicon (0.2 to 0.5 per cent.) and aluminium (0.25 to 0.3 per cent.), together with traces of iron. The metal does not contain oxide or chloride in solution, but in the sticks cavities containing these substances were occasionally found. The specific gravity of pure calcium is 1.52; in the samples examined, however, this was often as high as 1.59, owing to the presence of silicon. When melted under potassium chloride, a portion of the potassium is displaced, and is obtained as a crust on the metal-point when cold. It was not possible to observe the melting of calcium owing to the formation of a film of oxide, but the point at which it softens is 800° C. *In vacuo* the metal sublimes without melting and the sublimate consists of pure calcium. The vapour readily combines with the oxygen and nitrogen of the air, thus affording a means of obtaining high vacuum. —B. J. S.

Copper; Coating Metals with —. S. Cowper-Coles and Sherard Cowper-Coles and Co., Ltd., London. Eng. Pat. 28,590, Dec. 29, 1903.

THE articles to be treated, after being properly cleansed, are placed in a suitable receptacle, from which preferably the air has been exhausted, together with cuprous oxide or finely-divided metallic copper, and rotated or oscillated for an hour or more while being maintained at a dull red heat.—J. H. C.

Zinc and other Sulphides; Apparatus for Recovering from their Ores by the Wet or Chemical Process —. J. H. Gillies, Melbourne. Eng. Pat. 20,160, Sept. 19, 1904.

THE stream of tailings containing the mineral sulphides is made to flow down the slope of a funnel-shaped receptacle which contains the liquid chemical employed. The apparatus is so arranged that the incoming and outgoing cold liquid does not materially affect the temperature of the chemical liquid in the upper portion of the apparatus, which is heated by a steam jacket or other convenient

means. The waste particles escape by pipes placed at the bottom of the funnel. —J. H. C.

UNITED STATES PATENTS.

Precious Metals; Apparatus for Recovering —. V. Tunbridge, Newark, N.J. (Administratrix of J. Tunbridge, deceased). U.S. Pat. 777,159, Dec. 13, 1904.

THE apparatus consists of a supply channel having a backwardly-inclined screen at its discharge end, from which the pulp passes to a separator consisting of several sediment-collecting hoppers, the overflows of which are progressively higher towards the outlet, thence to a forwardly-inclined screen provided with means for holding soap, and finally to a filtering tank adapted to contain oil at its receiving end and filtering material between the oil and the outlet.—J. H. C.

Precious Metals; Method of Recovering —, from [Cyanide] Solutions. I. Anderson, Prescott, Ariz., Assignor to M. Scanlon, Whitehills, Ariz. U.S. Pat. 778,348, Dec. 27, 1904.

PRECIOUS metals are recovered from their cyanide solutions by adding soluble chlorides and sulphides, and then a mineral acid, such as sulphuric acid. The insoluble compounds of the precious metals formed are separated, and the cyanide solution is regenerated by the addition of lime, the latter process being applicable to any solution containing potassium sulphate and hydrocyanic acid. —E. S.

Metals; Precipitating —, from Cyanide Solutions, and Regenerating the Solutions. L. E. Porter, Camp Rochester, Cal. U.S. Pat. 778,547, Dec. 27, 1904.

ALKALINE cyanide solutions of metals are treated with zinc shavings, calcium hydroxide, and an ammonium salt; and after separation of the metals precipitated, the solution is regenerated by addition of an alkaline carbonate to precipitate part of the zinc as a double carbonate of calcium and zinc. Ores containing gold, silver and copper are leached with a cyanide solution, from which the gold and silver are precipitated by zinc; the copper is subsequently precipitated by adding ammonia and zinc dust, and the cleared solution is regenerated for re-use. —E. S.

Blast-Furnace. J. Coyne, Allegheny, Pa. U.S. Pat. 777,498, Dec. 13, 1904.

THE furnace has an outlet for the normal escape of gas, an explosion chamber connected thereto, and means for washing the gases as they pass through the chamber, and for separating dust. The explosion chamber has two compartments, and is provided with a water-seal to prevent the passage of gases from one to the other under normal pressure. Connected with the explosion chamber is a dust-collecting chamber, which is usually closed, but may be opened for cleaning when required.—J. H. C.

Furnace for Roasting, Smelting, &c. U. Wedge, Ardmore, Pa. U.S. Pat. 777,577, Dec. 13, 1904.

THE furnace is circular, and has a central hollow shaft open at the top and provided with one or more stirrer arms projecting therefrom into the treating chamber, the fastenings of the arms being accessible from the interior of the shaft. The shaft is surrounded by a refractory or non-conducting shell, which is closed by a flange at the top. The arms are provided with passages for the flow of cooling liquid.—J. H. C.

Brazing; Process of —, and Brazing Compound. L. R. Schaap, Loveland, Colo., Assignor to the National Brazing Compound Co., Denver, Colo. U.S. Pats. 777,546 and 777,547, Dec. 13, 1904.

THE parts to be united are sufficiently heated while applying a mixture of 2 oz. each of "prussiate of potash" and plaster of Paris, $\frac{1}{2}$ oz. of charcoal, 1 oz. of citric acid and 2 oz. of borax, and finally applying the brazing metal.—J. H. C.

Aluminium or Aluminium Alloys; Solder for —. R. Fortum and E. Sempurn, Madrid. U.S. Pat. 778,025, Dec. 20, 1904.

Aluminium or other Metals; Art of Reducing —. H. S. Blackmore, Mount Vernon, N.Y. U.S. Pat. 778,100, Dec. 20, 1904.

THE process consists, in general terms, in exposing oxy-compounds of metals "to the action of a reducing agent capable of liberating heat during reduction and utilising the heat so liberated by the employment of reducing agents absorbing heat during reduction, the said endothermic and exothermic reduction processes being so proportioned that the heat evolved by exothermic reduction will be sufficient or in excess of that required to maintain the endothermic reduction." Specifically, aluminium is reduced from aluminium oxide by exposing the latter to the action of magnesium and acetylene at a reacting temperature. (Compare U.S. Pat. 775,060 of 1904; this J., 1904, 1225.)—E. S.

Metallic Oxides; Process of Reducing —, with *Metallic Aluminium*. F. C. Weber, Chicago, Ill. U.S. Pat. 778,345, Dec. 27, 1904.

THE metallic oxide is mixed with aluminium, both in fine powder, and the mixture is "strongly dried by steam heat," "thereby completely and absolutely dehydrating the material and dissociating the oxide and sulphide molecules from the to-be-treated charge in one operation." The hot, dry mixture is then briquetted, and the briquettes are "hermetically sealed" preparatory to reduction of the charge. (Compare U.S. Pat. 705,727; and Fr. Pat. 324,534, both of 1902; this J., 1902, 1142; and 1903, 559.)—E. S.

Sulphides from their Ores; Apparatus for Separating —. J. H. Gillies, Melbourne. U.S. Pat. 778,747, Dec. 27, 1904.

SEE Eng. Pat. 20,159 of 1904; this J., 1904, 1150.—T. F. B.

Alloy. C. H. Bierbaum, Buffalo, N.Y. U.S. Pat. 778,398, Dec. 27, 1904.

THE alloy is composed of zinc (86 per cent.), copper (9.9 per cent.), aluminium (4 per cent.), and magnesium (0.1 per cent.).—E. S.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(A.)—ELECTRO-CHEMISTRY.

Persulphuric Acid; Catalytic Phenomena in the Preparation of —. G. Petrenko. J. russ. phys.-chem. Ges., 1904, 38, 1051—1058. Chem. Centr., 1905, 1, 6—7.

IN the electrolysis of sulphuric acid, the yield of persulphuric acid depends upon the platinum anode; this is oxidised and thus acquires catalytic properties, in consequence of which the amount of persulphuric acid is diminished. In presence of hydrochloric acid, the yield of persulphuric acid is nearly doubled. Iridium, when used as anode, is dissolved to a greater extent and gives distinctly lower yields of persulphuric acid than platinum.—A. S.

Bleaching Solutions [Sodium Hypochlorite]; Apparatus for the Electrolytic Preparation of —. G. Jaegle. Bull. Soc. Ind. Mulhouse, 1904, 74, 327—333.

THE apparatus consists of a rectangular vat, divided into a number of narrow compartments by glass partitions.

When working with an E.M.F. of 110 volts, two such vats may be used, each divided into 9 compartments. Each compartment is provided with a coil for cooling purposes, the temperature of the liquid being maintained at from 35° to 40° C. Carbon cathodes and platinum anodes are used. The electrolyte consists of a 10 per cent. solution of sodium chloride, to which is added a small quantity of rosin soap (200 to 400 grms. per cb. m.) and calcium chloride, the former to prevent reduction of the hypochlorite at the cathode. In a battery of 42 such vats, the power consumption has been found to average 6.4 kilowatt-hours per kilo. of available chlorine produced, the consumption of sodium chloride being 6.5 kilos. A series of trials extending over 9 months gave an average strength of hypochlorite solution of 16.56 grms. of available chlorine per litre, falling to 14.46 grms. per litre after 24 hours on the average. The current employed, at 110 volts, averaged 45.42 amperes, and the temperature was maintained at 38° C. The cost of the bleaching liquor thus produced works out at approximately the same as that of bleaching powder, calculating on the basis of available chlorine, viz., 0.4M. per kilo. of available chlorine.—T. F. B.

Boron; Reduction of Manganese Oxides by —. A new *Manganese Boride*. B. du Jassonneix. Comptes rend., 1904, 139, 1209—1211.

IN the electric furnace, manganese oxides are rapidly reduced by amorphous boron. With excess of oxide, the fused mass may contain as much as 97 per cent. of manganese, and can be filed, but with excess of boron, more granular and harder substances are obtained, containing up to 20 per cent. of boron. From these the author has isolated a definite boride, MnB, as a crystalline metallic powder of sp. gr. 6.2. Halogens and oxygen attack it at high temperatures; water (or steam) slowly decomposes it, evolving hydrogen, and acids attack it rapidly. Alkali hydroxides or carbonates at a red heat attack it, forming manganates and borates.—J. T. D.

Rotating Anode in Electro-Analysis; Use of the —. E. F. Smith, G. H. West and L. G. Kollock. XXIII, page 107.

Metals; Electrolytic Deposition of —, with *Rapid Stirring of the Electrolyte*. A. Fischer and R. J. Bodaert. XXIII., page 107.

ENGLISH PATENTS.

Electrodes for Accumulators with invariable Electrolyte. E. W. Jungner, of Norrköpping, Sweden. Eng. Pat. 21,402, Oct. 5, 1904. Under Internat. Conv., Oct. 7, 1903.

THE active mass of the electrode consists of non-conductive oxides or hydroxides, mixed with graphite which has been coated by electrolysis with a thin sheet of some conductive metal, such as nickel, which is indifferent to the electrolyte; the object being the lowering of the conductive resistance of the active mass.—R. S. H.

Galvanic Batteries. P. Möllmann, Berlin. Eng. Pat. 23,622, Nov. 1, 1904.

THE electrolyte is filled into the battery in a dry, non-active condition, so that the battery can be subjected to long storage without any premature corrosion of the electrodes; when required for use water is added. To prevent the hygroscopic dry electrolyte from taking up moisture, it is mixed with finely-powdered gum tragacanth.—R. S. H.

Cellular and Fibrous Substances; Treatment, by Impregnation, of —, and *Apparatus for the Purpose*. The Electric Timber-Seasoning and Preservation Co., Ltd., and J. H. West. Eng. Pat. 26,899, Dec. 8, 1903. IX., page 92

Electrolytic Hydrogen and Oxygen; Apparatus for Collecting, Separating, Drying or similarly treating —. P. Garuti and C. R. Pompili, Rome. Eng. Pat. 27,249, Dec. 12, 1903.

THE present invention is an improvement of the previously

described apparatus of the same inventors (this J., 1902, 778). A water-trap serves to retain the spray carried over by each of the separate gases, and to allow of the electrolyte running back into the cell. The gases afterwards pass through tubes in which heated coils of platinum wire serve to remove traces of oxygen or hydrogen from the respective gases.—R. S. H.

Chlorine; Manufacture of —, by Electrolysing Sodium Chloride, and Apparatus therefor. S. Leethann and E. G. P. Bousfield. Eng. Pat. 456, Jan. 7, 1904. VII., page 90.

Registering by Electrical Means the Progress of Several Physical Processes; Apparatus for Automatically—. Siemens and Co. Eng. Pat., 17,528, Aug. 11, 1904. I., page 77.

Electrolytic Process and Apparatus therefor [Alkali, &c., Manufacture]. C. P. Townsend, Washington, U.S.A. Eng. Pat. 18,403, Aug. 25, 1904.

SEE FR. PAT. 345,871 OF 1904; THIS J., 1905, 33.—T. F. B.

UNITED STATES PATENTS.

Furnace; Electric —. H. M. Howe, New York, Assignor to Elmer and Amend, N.Y. U.S. Pat. 778,194, Dec. 20, 1904.

THIS INVENTION CONSISTS OF A SPLIT CYLINDER, WHICH IS HOLLOWED TO FORM A HEATING CHAMBER, AND IN THE INNER FACE OF THE WALLS OF THE CHAMBER IS A SPIRAL GROOVE CARRYING A HEATING WIRE, U-SHAPED IN CROSS-SECTION. A CRUCIBLE FITS INSIDE THE CHAMBER. THE FURNACE HAS A COVER CARRYING A PLUG, THROUGH WHICH PASS WIRES CONNECTED TO A RESISTANCE ELEMENT, THE LATTER BEING PLACED IN GROOVES MADE INTERNALLY IN TWO BLOCKS INSIDE THE CRUCIBLE. (See also Eng. Pats. 28,780 and 28,782, 1903; this J., 1904, 666.)—B. N.

Hydrosulphurous Acid; [Electrolytic] Process of Producing Salts of —. A. Frank, Charlottenburg, Germany. U.S. Pat. 777,669, Dec. 20, 1904.

SEE GER. PAT. 125,207 OF 1899; THIS J., 1902, 51.—T. F. B.

Gases; [Electrical] Apparatus for the Treatment of —. E. E. Werner, St. Louis, Mo., Assignor to Electrical Purifying Co., Kansas. U.S. Pat. 777,987, Dec. 20, 1904.

IN AN ENCLOSED CHAMBER, WITH SUITABLE INLET AND OUTLETS, ARE A PAIR OF ELECTRIC TERMINALS, BETWEEN WHICH AN ARC IS ESTABLISHED. COMPRESSED AIR IS LED INTO THE CHAMBER AND IS ALLOWED TO EXPAND IN THE GAP BETWEEN THE TERMINALS, SO THAT THE ARC IS DEFLECTED AND ELONGATED TRANSVERSELY WITHOUT BEING BROKEN. THE VOLUME OF COMPRESSED AIR WHICH IS INTRODUCED, AND THE EXTENT OF DEFLECTION AND ELONGATION OF THE ARC, ARE REGULATED BY THE VOLUME OF THE GASES ESCAPING FROM THE CHAMBER.—B. N.

Gases from Air; [Electrical] Process of Generating —. E. E. Werner, St. Louis, Mo., Assignor to Electrical Purifying Co., Stafford, Kansas. U.S. Pat. 777,988, Dec. 20, 1904.

THE PROCESS IS CLAIMED, AS DESCRIBED IN THE PRECEDING ABSTRACT (U.S. Pat. 777,987), OF "GENERATING GASES FROM AIR" BY PROJECTING COMPRESSED AIR IN A TRANSVERSE DIRECTION INTO THE PATH OF AN ARC, AND REGULATING THE EXTENT OF DEFLECTION AND ELONGATION OF THE ARC, PROPORTIONATELY TO THE VOLUME OF AIR INTRODUCED, BY VARYING THE OUTFLOW OF THE TREATED GASES.—B. N.

Gases; [Electrical] Apparatus for the Treatment of —. E. E. Werner, St. Louis, Mo., Assignor to Electrical Purifying Co., Stafford, Kansas. U.S. Pat. 777,989, Dec. 20, 1904.

THE APPARATUS IS SIMILAR TO THE ONE DESCRIBED IN U.S. PAT. 777,987 (SEE ABOVE). THE TERMINALS ARE IN CONNECTION WITH THE SECONDARY OF AN INDUCTION COIL, AND THE CHAMBER COMMUNICATES WITH A CYLINDER PROVIDED WITH A PISTON WORKING AGAINST A SPRING. THE MOVEMENTS OF THE PISTON, WHICH ARE CONTROLLED BY THE GAS PRESSURE, VARY THE AMOUNT

OF THE SECONDARY IN CIRCUIT, AND THEREFORE VARY THE SUPPLY OF CURRENT PROPORTIONATELY TO THE SUPPLY OF GAS TO THE ARC. B. N.

Gases; [Electrical] Apparatus for the Treatment of —. E. E. Werner, St. Louis, Mo., Assignor to Electrical Purifying Co., Stafford, Kansas. U.S. Pat. 777,990, Dec. 20, 1904.

THE APPARATUS IS SIMILAR TO THAT DESCRIBED IN U.S. PAT. 777,987 (SEE ABOVE), THE AIR BEING COMPRESSED AND COOLED BEFORE BEING DELIVERED TO THE ARC, AND THE CURRENT FOR PRODUCING THE LATTER IS SUPPLIED FROM A TRANSFORMER PLACED IN A STORAGE CHAMBER FOR THE GASES. THE TRANSFORMER IS COOLED BY THE COMPRESSED GAS, BEFORE THE LATTER IS DISCHARGED INTO THE ARC BY A SUITABLE PIPE LEADING FROM THE STORAGE CHAMBER.—B. N.

Projecting Air against Electric Discharges; Device for —. E. E. Werner, St. Louis, Mo., Assignor to Electrical Purifying Co., Stafford, Kansas. U.S. Pat. 777,991, Dec. 20, 1904.

THE COMPRESSED AIR TO BE TREATED, AS DESCRIBED IN U.S. PAT. 777,987 (SEE ABOVE), IS INJECTED, BY MEANS OF A SUITABLE DEVICE, IN A NUMBER OF DIVIDED STREAMS OR JETS AGAINST THE SIDE OF THE ARC AND AGAINST THE TERMINALS.—B. N.

Refractory Material [Electrical]; Manipulation of —. E. Thomson, Swampscott, Mass., Assignor to General Electric Co., New York. U.S. Pat. 778,286, Dec. 27, 1904.

THIS INVENTION RELATES TO A METHOD OF PRODUCING TUBES, PLATES, OR OTHER ARTICLES, FROM QUARTZ OR OTHER ANALOGOUS REFRACTORY MATERIAL IN A FINELY-DIVIDED STATE. A REFRACTORY CONDUCTING BODY, HAVING THE DESIRED CONTOUR, IS SURROUNDED ENTIRELY OR PARTIALLY WITH A QUANTITY OF THE DIVIDED MATERIAL, AND THE CONDUCTING BODY IS HEATED BY PASSING THROUGH IT A CURRENT OF SUFFICIENT STRENGTH, IN ORDER TO PRODUCE FUSION OF THE PORTIONS OF THE REFRACTORY MATERIAL IN CONTACT WITH THE CONDUCTING BODY. THE FUSED MATERIAL IS SEPARATED FROM THE CONDUCTING BODY, WITHOUT DESTROYING THE FORM IMPARTED TO THE MASS BY THE LATTER.—B. N.

FRENCH PATENTS.

Galvanic Element, Zinc and Peroxide of Lead, with Positive Electrode Insoluble in Acid. R. Ziegenberg. Fr. Pat. 346,104, Sept. 7, 1904.

THE INVENTION CONSISTS ESSENTIALLY IN THE REPLACEMENT OF ORDINARY ZINC, AS A GALVANIC ELEMENT, BY AN ALLOY CONTAINING OVER 90 PER CENT. OF ZINC, WITH SMALL QUANTITIES OF PURE ENGLISH TIN, PURE LEAD AND MERCURY. THE PROPORTIONS RECOMMENDED ARE THE FOLLOWING:—94 PER CENT. OF ZINC, 2.5 PER CENT. OF TIN, 1.5 PER CENT. OF LEAD AND 2 PER CENT. OF MERCURY, THIS ALLOY RESISTING THE ACTION OF THE ACID EXCEPT WHEN THE CELL IS IN USE.—B. N.

Ammonia and Caustic Alkali; Method of Production of —, by Electrolysis. G. E. Cassel. Fr. Pat. 346,066, Sept. 3, 1904.

THE GASES, PRODUCED BY THE ACTION OF AN ELECTRIC DISCHARGE ON AIR, ARE ABSORBED IN CAUSTIC ALKALI SO AS TO FORM NITRITES OR NITRATES, AND THE SOLUTION IS ELECTROLYSED USING INSOLUBLE ELECTRODES WITHOUT A DIAPHRAGM. AMMONIA IS LIBERATED AS A GAS, AND THE CAUSTIC ALKALI IS RE-FORMED. THE YIELD IS IMPROVED BY ADDITION OF 5 PER CENT. OF LEAD NITRATE, AND NITRITES MUST BE PRESENT IN SUFFICIENT QUANTITY, BUT THESE ADDITIONS MAY BE DISPENSED WITH IF A SMALL CURRENT DENSITY IS USED AT THE CATHODE. LIME OR CALCIUM CARBONATE MAY BE USED INSTEAD OF CAUSTIC ALKALI AS THE ABSORBENT, AND THE CALCIUM NITRITE OR NITRATE IS AFTERWARDS TREATED WITH A SALT OF AN ALKALI METAL. THE NITRITE OR NITRATE OF THE ALKALI METAL IS THEN TREATED ELECTROLYTICALLY TO OBTAIN PURE CAUSTIC ALKALI.—B. N.

(B.)—ELECTRO-METALLURGY.

Aluminium Alloys; Thermo-Electricity of —. H. Pécheux. Comptes rend., 1904, 139, 1202—1204.

THE AUTHOR HAS DETERMINED THE THERMO-E.M.F. OF THE

various aluminium alloys prepared by him as compared with copper, the cold junction being always at 17.5 C., the hot junction at 100, 180, and 380 C. All the metals,

single and alloyed, were employed, cast into rods, without any mechanical treatment. The following are the results expressed in microvolts:—

Copper Galvanoplastic Process without Stirring and Heating. S. von Maximowitsch. *Elektrochem. Zeits.*, 1904, 11, 165–166. *Chem. Centr.*, 1904, 2, 1773.

THE author, in order to avoid heating or stirring the electrolyte, arranges the electrodes horizontally, the anode above the cathode, so that the concentrated solution of copper sulphate flows directly from the former to the latter. A net of silk gauze is suspended between the electrodes to retain the anode mud. In the author's experiments, the electrolyte consisted of a solution containing 220 grms. of copper sulphate crystals and 25 grms. of sulphuric acid per litre, the current density was 6–10 amperes per sq. decm., the E.M.F. 0.8 volt. per ampere of current-density, and the distance between the electrodes, 8 cm. The deposit was smooth, bright and tough. The method is not patented.—A. S.

ENGLISH PATENTS.

Magnetic Separators for Ores or the like. J. T. Dawes. Prespatyn, Flintshire. Eng. Pat. 27,298, Dec. 14, 1903.

THE material to be sorted is delivered on to a moving surface, such as the periphery of a rotating drum, immediately above which is a revolving disc rendered magnetic by a magnet arranged above it. Another magnet has its poles arranged within the drum opposite to the upper magnet poles, and of opposite polarity, so that an intense magnetic field is provided. The upper magnet poles have projections extending over the disc and over the sides of the drum, above shields kept in close contact with the sides of the drum by springs or other devices, in such a manner that the shield is between the drum and outer extremity of the magnet pole, so that the magnetic particles collecting on the underside of the disc at the outer extremity of the magnet projections, are kept

from rubbing against the drum, and from being carried away with it, and are constrained to fall into the hopper provided to receive them.—E. S.

Amalgamating and Coating Metal Surfaces with Metals by the aid of Electricity; Apparatus for —. H. M. W. P. Johnson, Blackheath, Kent. Eng. Pat. 3087, Feb. 8, 1904.

A MOVABLE electrode is provided with a covering of some absorbent material on the face next to the object to be coated, and is supplied with a fluid electrolyte. The arrangement has a easing or shield at its edges for preventing the escape of the electrolyte.—R. S. H.

Copper Articles; Method of Treating [Coating] —. S. Richart, Mainz, Germany. Eng. Pat. 22,623, Oct. 20, 1904.

THE articles to be treated are highly polished, and then electro-coated with arsenic or antimony in a bath composed of 5 kilos. of sodium arsenate or of an antimony salt, and 5 kilos. of potassium cyanide dissolved in about 80 litres of water, to which 2½ kilos. of ferric chloride are added. They are then heated to "incandescence or glowing" and again polished, when the surfaces have an enamelled appearance, well adapted to resist physical and mechanical influences, and present shades of colour from red to violet.—J. H. C.

UNITED STATES PATENT.

Magnesium; [Electrolytic] Production of Metallic —. I. L. Roberts, Assignor to J. T. Morehead, both of New York. U.S. Pat. 778,270, Dec. 27, 1904.

THIS invention consists in fusing magnesium fluoride, or the fluoride and another compound of magnesium, such as the chloride, together with one, two or more chlorides of the alkali metals, such as lithium. The fused mixture is electrolysed in an atmosphere composed of the gases produced by the electrolysis.—B. N.

FRENCH PATENT.

Sulphides, Arsenides and Antimonides: Treatment [Reduction] of Metallic —. N. Dekker. Fr. Pat. 345,834, Aug. 13, 1904.

NASCENT hydrogen produced particularly by the electrolysis of water, is employed for the reduction of the natural sulphides, arsenides, and antimonides. In each case a thin layer of the material containing the sulphide particles is brought into sufficiently prolonged contact with the nascent hydrogen produced at the surface of the negative electrode. The electrolyte employed is a 10 per cent. solution of sulphuric acid or a similar solution of a hydrated alkali; the electrodes may be of graphite, lead, or platinum.—J. H. C.

Reduction or Oxidation of Solid Boilers [Ores, &c.] by means of an Electric Furnace; Process for the —. K. Birkeland and S. Eyde. Fr. Pat. 345,969, Sept. 1, 1904. Under Internat. Conv., Sept. 19, 1903.

SEE Eng. Pat. 29,003 of 1904; this J. 1905, 34.—T. F. B.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

Δ^o-Oleic Acid. H. R. Le Sueur. Chem. Soc. Trans., 1904, 85, 1708—1713.

Δ^o-OLEIC acid is produced together with α-hydroxystearic acid by boiling α-bromostearic acid with 30 per cent. alcoholic potash. The α-hydroxystearic acid is separated by crystallisation from light petroleum, and the Δ^o-oleic acid is isolated from the mother-liquor by fractional crystallisation, first from ethyl acetate and then from light petroleum. Δ^o-Oleic acid has the structural formula $C_{15}H_{31}.CH:CH.CO_2H$; it melts at 58°—59° C., and solidifies at 56°—55° C. When oxidised in hot alkaline solution with a 1½ per cent. solution of potassium permanganate, it yields palmitic acid, but by careful oxidation with a 1 per cent. solution of the reagent at 0° C., α-β-dihydroxystearic acid, $C_{15}H_{31}.CH(OH).CH(OH).CO_2H$, is produced. This last-named acid melts at 126° C., and solidifies at 124°—123° C.; it is appreciably soluble in boiling water. The author discusses the *iso*-oleic acid of M. C. and A. Saytzeff (J. pr. Chem., 1888, 37, 269), and agrees with Ponzio (this J., 1904, 942) that this acid has not the double linking between the α- and β- carbon atoms, and that therefore, the Saytzeff's formula for oleic acid, based entirely upon their view as to the constitution of *iso*-oleic acid, is incorrect. The elimination of the Saytzeff's formula, as also the work of Barnich (Ber., 1894, 27, 172) and others, appears to render it certain that oleic acid has the constitution $CH_3(CH_2)_7.CH:CH(CH_2)_7.CO_2H$.—A. S.

Tobacco Seed Oil. G. Ampola and F. Scurti. Gaz. chim. ital., 1904, 34, 315—321. Chem. Centr., 1905, 1, 35—36.

FROM the seeds of *Nicotiana tabacum* there is obtained, by pressure, 9—10 per cent., and by extraction, 30—32 per cent. of a yellow oil with a pleasant odour, different from that of tobacco. The oil has the sp. gr. 0.9232 at 15° C., m.p. —25° C., is soluble in 31 parts of absolute alcohol, and mixes in all proportions with ether, chloroform, carbon bisulphide and oil of turpentine. It begins to distil at 150° C. It has the iodine value 118.6; free fatty acids (as oleic acid), 3.49 per cent.; saponification value, 190; saponification value of non-volatile fatty acids, 203 (by Tortelli and Pergami's method, mean molecular weight being calculated as 275.8; this J., 1902, 1187); Hehner value, 94.73; Maumené test in Tortelli's apparatus (this J., 1904, 668), 100. In Livache's test, the oil absorbed 5.01 per cent. of oxygen in 2 days, 5.61 in 4, and 6.84 per cent. in 14 days. In the elaidin test, the oil remained liquid and a whitish precipitate was produced. The fatty acids of the oil are chiefly oleic acid (about 25 per cent.), linolic acid (about 15 per cent.) and palmitic acid (about 32 per cent.), together with small quantities of stearic acid.—A. S.

Sesame Oil; Detection of —, in presence of Dyestuffs that give a Red Coloration with Hydrochloric Acid. G. Fendler. XXIII., page 108.

UNITED STATES PATENT.

Wax Emulsion and Process of Producing same. H. H. Church, Bellows Falls, Vt., Assignor to Casein Co. of America, New Jersey. U.S. Pat. 778,115, Dec. 27, 1904.

PARAFFIN wax (50 parts), stearic acid (50 parts) and Chinese vegetable tallow (50 parts) are melted in water with the aid of heat, a solution containing trisodium phosphate (5 parts) and caustic soda (5 parts) is added, and the mixture is boiled for half an hour or more, with continual agitation, until frothing has ceased.—A. S.

FRENCH PATENT.

Fat; Extraction of —, from Seeds or Oleaginous Fruits, by Diffusion. C. Tanquerel. Fr. Pat. 345,849, Aug. 25, 1904.

IN this process, which is specially intended for the extraction of olive oil, claim is made for the use of a solution (sp. gr. 1.025—1.100) of the chloride of a metal of the alkali or alkaline-earth group. The paste-like mass of olives obtained by the usual methods is introduced into a tank containing a definite quantity of the saline solution, which is maintained at a temperature not exceeding 65° C., by means of a steam coil. Further quantities of the saline solution are continuously forced in through pipes at the bottom of the tank, and the mixture is agitated by means of currents of compressed air. The solid particles collect at the bottom, whilst the fat rises to the surface and falls through an outlet tube near the top of the tank.—C. A. M.

(C).—INDIA-RUBBER, &c.

India-rubber; Grinding of Hard ——. G. Springer. Gummi-Zeit., 1904, 19, 249—250.

HARD rubber in the form of powder is best obtained by passing the material to be treated through crushing and grinding rolls. The preliminary grinding is done on grooved friction rolls, the speed of the same being 7 to 8 and 21 to 24 revolutions per minute respectively. The resulting mass is ground to the necessary degree of fineness on smooth calendar rolls revolving 6 and 8 times per minute respectively. Previous to grinding, the rubber is freed from foreign materials, as far as possible, and washed in warm water. It is then placed in a metal tray and introduced into a vulcaniser to remove moisture, and to thoroughly soften it, when it is ready for the crushing and grinding process. It is advisable, after grinding, to remove any particles of iron by means of powerful magnets. The ground material is passed through cylindrical sieves, the coarse residue being returned to the mill. As the finished powder is liable to spontaneous ignition, it should be carefully cooled before being stored. Owing to the large proportion of hard rubber powder used in hard rubber mixings (up to 50 per cent.) the supply is not equal to the demand, and it is specially prepared by mixing soft floating waste rubber with 30 per cent. of sulphur, heating the mixture in thin layers in a vulcaniser for several hours at a temperature of 135°—140° C., grinding coarsely, and reheating for several hours at the same temperature.—J. K. B.

Hides and Skins; Process of Tanning ——. I. Sonoff and M. Zwerckoff. Fr. Pat. 346,098, Sept. 7, 1904.

THE hides or skins prepared ready for tanning are first immersed for two hours in a solution of common salt, and afterwards placed in a closed chamber and subjected to the fumes of burning straw, dried leaves or other vegetable matter for 10 to 20 hours; the goods are finally immersed in a dilute solution of sulphuric acid.—M. C. L.

XV.—MANURES, Etc.

Perchlorate in Commercial Sodium Nitrate. H. Pellet and G. Fribourg. Biod. Centr., 1904, 33, 798—803; from Ann. Science Agron., 1902-3, 8, 199.

THE amounts of perchlorate generally present in commercial sodium nitrate vary from traces to 1.5 per cent. Some samples contained, however, 3.2 per cent., or even 6 per cent., reckoned as potassium salt.

According to P. de Caluwe vegetation is injured by less than 1 per cent. of sodium perchlorate, whilst potassium perchlorate and chlorate are much less injurious. Sodium nitrate which contains perchlorate seems to contain only a little chlorate. In analysing samples, it is desirable to determine the potassium as well as the perchlorate and chlorate.

The following method of Vincente and Lafitte for the detection of chlorates is given. The solution of sodium nitrate is treated successively with a few drops of a solution of aniline (1 c.c. in 40 c.c. of water), and an equal volume of hydrochloric acid of 22° B. In presence of the smallest traces of chlorate a reddish-violet coloration is produced which turns to an intense blue.—N. H. J. M.

XVII.—BREWING, WINES, SPIRITS, Etc.

Barley Plant; Distribution of the Nitrogen in the ——. E. Jalowetz. Woch. f. Brau., 1904, 21, 840—845.

PREVIOUS researches having shown that the proportion of nitrogen in the barley corn is greater at the basal end than at the point, and is greater at the point end than at the middle of the corn, the author has turned his attention to the distribution of nitrogen in corns from various parts of the same ear. The present experiments were made with the Hanna variety of barley; the selected ears were cut in

some cases longitudinally and in other cases transversely to equal halves. The proportion of moisture was the same in all parts of the ear, and different ears from the same field gave corns containing the same proportions of moisture. The proportions of nitrogen in the corns of the right and left halves of the same ear were identical; in the corns of the upper half of the ear always contained higher proportion of nitrogen than the corns from the lower half of the same ear. This difference, however, is solely due to the fact that the corns of the upper half are smaller than those of the lower half, and it was determined that the absolute quantity of nitrogen is the same in every corn of the ear, or, in other words, the percentage of nitrogen multiplied by the weight of the corn is constant for the same ear. The proportions of nitrogen in the corns of different ears in the same field vary between wide limits, consequently the method of valuation which depends on the percentage of nitrogen in a sample of barley is not invariably reliable; there is, however, a tendency to equalisation in samples taken from bulk as compared with those taken from individual ears. The ears of the main stems of a single plant contain the same percentage of nitrogen, but the ears of the side stems, which are generally scarcely ripe and are filled with undersized corns, contain a higher percentage of nitrogen than those of the main stems.—J. F. B.

arch; Diastatic Coagulation of —. [*Amylo-coagulase*]. A. Fernbach and J. Wolff. *Comptes rend.*, 1904, 139, 1217–1219.

In previous experiments potato starch-paste, prepared by heating under pressure at 120° C., was not always coagulated by infusions of certain raw grains, although these extracts undoubtedly contained the coagulating enzyme, amylo-coagulase. This anomaly is now explained by the observation that the starch must exist in definite condition of liquefaction before coagulation can be produced by the enzyme in question. If the starch be treated with a malt infusion which has been previously heated for 10 minutes at 75° C. in order to destroy the coagulating enzyme without destroying the liquefying diastase, coagulation can be readily effected by infusions of raw barley, wheat or rye, which by themselves are incapable of producing coagulation. Since, however, the process of heating at 75° C. does not completely destroy the saccharifying diastase of the malt, it is important that the quantity of heated malt infusion and the time of its action should be carefully regulated. An infusion of oats contains no amylo-coagulase, but it does contain a starch-liquefying diastase; such an infusion can therefore be employed in place of the heated malt extract for bringing the starch into a condition suitable for coagulation by infusions of raw barley, wheat and rye. This reaction may be utilised as a qualitative test for the presence of a liquefying diastase or a coagulating enzyme in plant-infusions. Further, it has been found that the liquefying action of the heated malt extract may be imitated by heating the starch-paste at 45° C. under pressure, and that a paste so liquefied is coagulated by the raw grain extracts directly.—J. F. B.

Yeasts; Acclimatisation of —. to *Antiseptics*. J. Effront. *Monit. Scient.*, 1905, 19, 19–24.

On examining a series of brewery yeasts prepared in sterilised wort containing increasing amounts of ammonium fluoride, it was found that the nitrogen content remained practically constant, whilst the percentages of ash and lime in the yeasts increased with increasing amounts of fluoride. (For information on the properties of yeasts acclimatised to fluorides see this J., 1892, 50, and 1894, 968 and 1079.) It would thus appear that this acclimatisation to fluorides increases the affinity of the cells for mineral matter, and that this increased accumulation of lime renders the fluoride harmless by converting it into insoluble calcium fluoride. Brewery yeasts can be similarly acclimatised to considerable quantities of formaldehyde: top fermentation yeasts are less sensitive to the action of formaldehyde than bottom fermentation yeasts. The action of formaldehyde is manifested by a retardation in the commencement of

fermentation, and by a diminished growth of yeast. A wort containing 1.5 gram. of formaldehyde per litre, when allowed to stand with unacclimatised yeast at 30° C. will not ferment for some weeks: on prolonged contact, the fermentative power of the yeast is still further weakened, and finally the yeast is rendered incapable of inducing fermentation in a pure wort. The greater the extent to which a yeast has been acclimatised to formaldehyde, the more acid will be formed in the subsequent fermentation of a wort, the aldehyde being oxidised to formic acid. Acid ferments develop more rapidly in a wort in presence of yeasts acclimatised to formaldehyde; this contrasts strongly with the behaviour of yeast acclimatised to fluorides, the presence of which increases the resistance to acid ferments of worts containing a fluoride. The acclimatisation of yeasts to formaldehyde is attributed solely to the development of a special function which facilitates the rapid oxidation of the aldehyde, since it is experimentally demonstrated that this oxidation always precedes, and is quite independent of, the fermentation. In presence of a yeast which has been acclimatised to formaldehyde, the fermentation of a wort is found to be much more rapid than with a fresh yeast.—T. F. B.

Yeast Enzymes. K. Schiga. *Z. physiol. Chem.*, 1904, 42, 503; *Woch. f. Brau.*, 1904, 21, 834.

The presence in yeast of an enzyme, nuclease, which is capable of splitting up nucleic acid, has already been recorded by various investigators. The author has studied it by digesting yeast cell-juice with guanine in presence of toluene for 40 hours in a warm chamber. The guanine was split up during the digestion with the formation of adenine and a little xanthine. He also studied the action of yeast juice upon arginine by digestion under similar conditions for four days. The quantity of arginine decreased during the digestion, whilst that of its decomposition products, ornithine and urea, increased. Yeast therefore secretes the enzyme arginase, which is an enzyme occurring in animal organs. Guanidine, of which substance arginine is a derivative, is not split up by arginase.—J. F. B.

"Chinese Yeast"; A New Kind of —. K. Saito. *Centr.-Bl. f. Bakter. u. Parasitenk.*, 1904, 13, 153–161. *Chem. Centr.*, 1905, 1, 40.

The wheat-flour cake used in the preparation of the Chinese beverage "Shao-hing-Chew" contains, besides the ordinary mould fungi, two new kinds of *Rhizopus*, named *Rhizopus chinensis* and *R. tritici* respectively. The author describes the morphological and physiological properties of these mould fungi. They saccharify starch with the production of alcohol and esters, and also liquefy gelatin, *R. chinensis* more quickly than *R. tritici*. They cause an evolution of gas when sown in wort, but not in sugar solutions. (See also this J., 1900, 839; 1901, 377, 757.)—A. S.

Mashing; Influence of Gypsum on Starch and Albumin Conversion in —. W. Windisch und H. Boden. *Woch. f. Brau.*, 1904, 21, 775–776, 787–789, 799–801, 823–827, 835–838.

The addition of gypsum to the mashing water exerts a retarding influence on the diastatic power of the malt, which is more marked the more the diastase has been weakened by other causes, such as high curing and high mashing temperatures. This influence on the diastatic power involves a reduction of the attenuability of the wort, which reduction is the same with either Saaz or Froberg yeast; this is solely due to the modified conversion of the starch, and is not observed when the gypsum is added after mashing. The fungus *Amylomyces Rouxii* converts the unfermentable starch products, due to the gypsum, into readily fermentable products. No reduction in the attenuability of the wort is observed with very highly attenuating yeasts like *S. Pombe* when gypsum is used.

The presence of gypsum causes an increase in the nitrogen of the wort, depending on the quantity of gypsum and the temperature of mashing; this increase may amount to as much as one-fifth of the total nitrogen.

The increased quantity of nitrogen does not include albumin, but consists solely of decomposition products, chiefly amino-acids. Thus the gypsum favours the action of the malt-peptase, making it more rapid and more profound. The increased quantity of nitrogen is, however, of no benefit to the yeast, since an excess of yeast-nutrients is always present. When gypsum is used the tendency is to coagulate more albumin in the wort copper than under ordinary conditions.

The authors' conclusions are not favourable to the artificial hardening of brewing waters by gypsum. The starch conversion products, obtained by the influence of gypsum on the diastase, are not of the slowly fermentable maltodextrin type, but are unfermentable by brewer's yeast. In any case if limited attenuations are desired, they can be obtained much more surely by other means, e.g. the "spring" mashing process. Under ordinary brewing conditions the influence of gypsum is only very slight, and large quantities must be used to produce marked effects. The increase of the nitrogenous matters of the wort, which gypsum produces, is not required, and is perhaps even harmful. Gypsum also favours a secondary coagulation of albumin when the wort is re-boiled, or when the beer is pasteurised: it causes a tendency to glutin-turbidities, and does not improve the "break." The only points that can be urged in its favour are that it possibly improves the flavour of the beer and that it affords a supply of lime to the yeast, both of which effects would be obtainable if the gypsum were added to the wort in the copper instead of to the mashing liquor.—J. F. B.

Alcoholic Fermentation: Behaviour of Albuminoids during —. L. Iwanoff. Z. physiol. Chem., 1904, 42, 464. Woch. f. Brau., 1904, 21, 845—847.

Is the fermentation of solutions of pure sugar, free from added nutrient matters, the author determined that the quantity of albumin introduced with the yeast was the same after fermentation as before, in spite of the fact that the yeast contained a sufficient supply of nitrogenous matters of a non-albuminoid nature. There was thus neither a breaking down nor a synthesis of albumin during the fermentation, although when the fermentations were conducted with the addition of asparagine, a considerable quantity of albumin was produced therefrom. Hence yeast is not capable of regenerating albumin from all of the products of the decomposition of the latter, and a continuous metabolism and catabolism of albumin cannot be maintained without the introduction of external nutrient. For instance, when yeast had been starved by storage under water until it contained a considerable proportion of nitrogenous metabolic products, it was found that on subsequent addition of sugar, the quantity of albumin regenerated from those products only amounted to 40—60 per cent. of the albumin originally present. From this fact it is concluded that the constancy of the quantity of albumin during alcoholic fermentation in pure sugar solutions can only be attributed to the total inactivity of the albumin portion of the system. According to the author's observations, the presence of fermentable carbohydrate exerts a great influence on the digestion of the yeast-albumin by the proteolytic enzyme. Yeast killed by pasteurisation, and subjected to conditions favourable to auto-digestion, immediately after it had been fermenting a solution of cane sugar, was digested with only one-half the rapidity as compared with yeast which did not contain any of the fermented liquid, and the former yeast was also found to be capable of retarding the auto-digestion of the latter when the two were mixed. Hence it is concluded that an "anti-proteolytic" substance is produced during the fermentation of sugar. This substance appears to be one of the volatile products of fermentation, since it is eliminated by boiling in the ordinary manner, but not by boiling under a reflux-condenser; probably it is an aldehyde or ester.—J. F. B.

Brewing Vessels: Volumetric Method of Gauging —. W. Windisch. Woch. f. Brau., 1905, 22, 1—4. (See this J., 1905, 38.)

The author defends the method for gauging large brewing vessels by making a solution of thiosulphate up to a certain

mark in the vessel and titrating this solution with iodine standardised against a solution of the same thiosulphate prepared carefully in the laboratory. In order, however, to obtain sufficiently accurate results, it is necessary to work with extreme care. It is best to add most of the iodine required in the form of a $N/10$ solution, and complete the titration with $N/100$ iodine solution from second burette. The solutions and measuring vessel must be free from grease, the temperature of the solution must be maintained constant, and 8 or 10 titrations of the same solution should be made. It is possible to gauge a large vessel with errors not exceeding 0.15 per cent. by this method, which is strongly recommended where the method of weighing the water-contents of the vessel is impracticable.—J. F. B.

Saccharin in Wine: Qualitative Detection of —. MacKay Chace. XXIII, page 105.

ENGLISH PATENTS.

Drying Granular and other Materials [Brewers' Grain, &c.]. Apparatus for —. H. H. Lake, London. From C. H. Caspar, Wilkes-Barre, Pa., U.S.A. Eng. Pat. 23,066, Oct. 26, 1904.

The apparatus is intended for drying brewers' grains and like loose materials. It consists of a drum mounted on trunnions and capable of revolving in an outer shell, and provided with "paddles or agitators" around its circumference. Through the drum passes a series of pipes through which are led hot gases coming from a furnace. Above this drum is mounted a similar smaller drum as a shell, provided at one end with a screw conveyor, and with an inlet pipe for the hot gases issuing from the lower drum. The material to be dried is fed from a hopper through the screw conveyor into the upper drum, any adhering water being squeezed out. It then meets the comparatively cool gases from the lower drum, and dries without blistering. From the exit-end of the upper drum it then falls in the lower drum, and is completely dried whilst passing through, by the heat from the hot furnace gases. Suitable means for revolving the drums and for creating a draught for the gases are provided.—L. F. G.

Mashing Apparatus and Filters for any Liquids. Selg. New York. Eng. Pat. 3080, Feb. 8, 1904.

The mash-tun or filtering vessel consists of a suitable shell with a perforated false bottom situated at some distance above the real bottom, so as to form a chamber beneath for the filtered liquid. The discharge pipe communicates with the bottom of this filtering chamber and carries a U-shaped trap with one leg much shorter than the other. The short leg branches out from the discharge pipe, whilst the long leg forms an external stand-pipe parallel with the wall of the shell. A second discharge cock is fitted to the U-shaped pipe at the same level as the false bottom, whilst the stand-pipe can be connected at will with the upper part of the interior of the shell. Filtration is thus effected with but very slight difference in pressure, thus avoiding the packing of the material against the false bottom.—J. F. B.

Beer: Impts. in Brewing —. L. Nathan, Zurich. Eng. Pat. 20,534, Sept. 23, 1904. Under International Conv., Oct. 7, 1903.

STERILISED wort, which is agitated during fermentation, is supplied with a quantity of air less than that which would be spontaneously absorbed by the wort if allowed to cool under normal atmospheric conditions. The hot wort is run into a sterilised vessel and allowed to cool therein; when the temperature has fallen to about 50° C. the air supply is cut off and the upper part of the vessel is connected with a supply of sterilised carbon dioxide. When the fermentation temperature is reached a measured quantity of yeast, bearing the correct proportion to the volume of air supplied, is introduced. If the agitation of the wort during fermentation be effected by a stream of carbon dioxide, the quantity of air employed must be increased in order to overcome the retarding influence of the carbon dioxide.—J. F. B.

UNITED STATES PATENT.

Annulator and Regulator [for Alcohol Rectifying Apparatus]. E. Guillaume, Paris. U.S. Pat. 778,150, Dec. 27, 1904.

Rectifiers; Apparatus for Continuous Rectification of —. L. A. Barbet. Second addition, dated Aug. 25, 1904. No Fr. Pat. 343,488, April 16, 1904. (See this J., 1904, 039.)

THE phlegms are treated in a separate column in the upper part of which the aldehydes and esters are mainly removed. In the lower part of the column the phlegm is mixed with sufficient lime-water to give it a distinctly alkaline reaction. The remainder of the aldehydes and esters is thus decomposed together with the ammonia and basic compounds. Before entering the main rectifying column, the phlegm is subjected to the action of carbon dioxide in order to precipitate the lime and render the liquid neutral. —W. P. S.

Alcohol; Manufacture of —, for Illuminating Purposes. B. Plehn. Fr. Pat. 345,777, Aug. 23, 1904. H., page 80.

Alcohol; Process for Denaturing —. T. Heidlberg. Fr. Pat. 346,152, Sept. 9, 1904.

ALCOHOL is denatured with an alcoholic solution of crude purified animal gall, either alone or in conjunction with other substances. If the alkaline residues of the gall be desirable, the glycocholic and taurocholic acids may be separated from the gall and used in the free state.—J. F. B.

XIX.—PAPER, PASTEBOARD, Etc.

Paper Pulp; Yarn from —. E. Hanansek und R. Zaloziecki. Chem.-Zeit., 1905, 39, 3—4.

PAPER-PULP (wood-cellulose) intended for the spinning of yarn, should be prepared in the beating engine in such a way that the fibres are not shortened, but merely drawn out and isolated from the fibre-bundles by a brushing or rubbing action. The authors have examined samples of yarn from two of the German mills. Under the

microscope these yarns were found to be prepared from pure, unbleached cellulose from coniferous wood, showing only traces of lignification. In one product the fibres were rather short with blunt ends, and had the appearance of having been subjected to rather severe beating; the shortening of the fibres might be partly attributable to the preliminary chemical treatment. The ultimate fibres were sufficiently isolated, and in many cases the longitudinal rows of pits on the tracheids were discernible. Certain typical modifications of the fibres were detected; a remarkable alteration was shown by the presence of large holes, like pores, in some of the places where the pits had been, some of the pits in the row being still unchanged; in side view these damaged fibres showed toothed edges. A few of the fibres had spiral net-work markings, like those of cotton fibres. The mechanical treatment due to the twisting of the yarn was found to have left its mark on the individual fibres; the pits and holes occurred in spiral rows, and the spiral deformation was visible, not only in the surface markings but also in the side contours, in proportion to the tightness of the twist. In addition to the spiral lines of deformation, transverse torsion lines were also observed. Between crossed Nicols the fibres appeared bluish-white, whilst the lines of deformation showed interference colours on a red ground.

In another make of yarn the fibres showed fibrillae, the pits were not easily discernible, there were no holes, and the spiral deformation of the rows of pits varied in degree.

—J. F. B.

Rosin Size: Proportion of Alkali in Preparing —. P. Klemm, *Wochenbl. f. Papierfab.*, 1904; through *Paper and Pulp*, 1905, 10, 18.

As rosin never consists of pure sylvic acid and always contains a certain quantity of moisture, it never requires the theoretical quantity of alkali for saponification (13.2 per cent. of caustic soda). In practice the most convenient proportion of alkali to employ is 11.2 per cent. of caustic soda, or its equivalent in carbonate. When this quantity has been used, and when the saponification is properly effected, the resulting size gives clear solutions in all proportions, provided the water be soft and free from carbon dioxide. There is no limit to the proportion of free rosin that can be taken up by the size, but until the introduction of Erfurt's process, the workable limit of free rosin was about one-third of the combined rosin. The following table shows the proportions of free and combined rosin when different proportions of caustic soda are employed:—

For Saponification of 100 lb. of Rosin.	For every 1 lb. of Rosin—	
	Combined.	Free.
6 lb. of caustic soda	364 lb.	636 lb.

—J. F. B.

Blotting Papers: Manufacture of —. C. Beadle and H. P. Stevens. *Paper and Pulp*, 1904, 9, 717–729.

THE authors show that the Charlottenburg method of testing blotting papers, by measuring the rapidity of the rise of water by capillary absorption in a strip, is not a sufficient guide to the value of a paper. They show that the capillary properties of a paper so determined are directly proportional to the volume of the air spaces between the fibres ("bulking properties"). But the value of a blotting paper depends also on the number of times it can be used whilst still retaining its bibulous qualities, and here the chemical nature of the ink comes into play. Blotting paper is best tested by dropping 1 c.c. of a ferro-tannic ink upon its surface in the form of a blot, drying the paper, and then testing the absorbent properties of the blot by drawing ink strokes across it in various directions. In many cases an external zone or

fringe is thus detected which is entirely incapable of absorbing a further quantity of ink, whilst the central portion of the blot is still absorbent. The diameter of this non-absorbent zone relatively to the diameter of blot is inversely proportional to the value of the blotting paper; in a series of tests of different makes the diameters of the non-absorbent zones varied from 1.7 to 1.1 per cent. of the total diameter. This zone-form property has no connection with the capacity of the paper for absorbing water as tested in the usual way. The authors have found that the cause of the non-absorbent zones lies in the basic residues contained in the paper; these basic matters include lime, iron oxide and alumina which neutralise the acidity of the ink, and are derived chiefly from the water, but also from the materials used in manufacture. A process has been devised whereby the basic constituents are removed and partly neutralised in the half-stuff hollander. It is important, however, that the treated pulp should subsequently be diluted and bleached with softened water and sodium hypochlorite. Many colouring matters, used in the manufacture of coloured blotting papers, have a great tendency to cause these non-absorbent zones, e.g., ultramarine, certain mineral colours and aniline dyestuffs. It has frequently been found that paper, which has been prepared so as to be free from zone-forming constituents, has developed the property of forming zones after storage owing to secondary reactions and dissociations of residual chemicals.—J. F. B.

Parchment Paper Containing Boric Acid. *Papier-Zeitung*, 1904, 29, 3644.

K. FISCHER has found that boric acid is frequently employed for the preservation of parchmentised paper, and that such paper is in general use for wrapping butter, margarine and other foods (*Z. Unters. Nahr. u. Genussmittel*, 1904). Boric acid is an excellent antiseptic for preserving parchment paper from mildew, and, in the opinion of many experts, it is perfectly unobjectional since only a small proportion is necessary, and it is inconceivable that more than a mere trace could be transferred to the articles of food round which the paper is wrapped. This preservative has, however, been forbidden by German law, and is not now employed in grease-proof papers manufactured in that country.—J. F. B.

ENGLISH PATENTS.

Paper and Pulp Making Machines. S. Milne, Edinburgh. Eng. Pat. 28,611, Dec. 30, 1903.

THE invention relates to the combination of two or three Fourdrinier wires, arranged to deliver their webs of paper in a single plane so that all the webs may be caught together to produce a single compound web of paper. In the simplest form, one or two Fourdrinier wires, each with independent shake and other fittings, are arranged above an ordinary Fourdrinier machine, and their delivered ends are brought down vertically or at an angle so as to coincide with the lowest web. In another form, the three webs are coupled, one above the other, on a single overhead felt.—J. F. B.

FRENCH PATENT.

Solutions; Apparatus for Pouring uniformly any liquid on to a continuously moving table or surface [*Paper Manufacture*]. R. Kron. Fr. Pat. 345,832, Aug. 12, 1904.

T apparatus is devised for pouring out solutions of oil, casein, glue, clay, colours, gum, or similar substances on to paper, tissues or like materials. The solution flows from a chamber provided with a stirrer through a series of adjustable openings into a second vessel, in which any scum or air bubbles are destroyed by means of an injector apparatus. The solution then flows into a flat distributing vessel which is kept at a suitable inclination to the horizontal, so that on leaving the vessel the solution has acquired a velocity equal to that of the moving surface on to which it is to be distributed. The distributing vessel is provided with an elastic bottom, and with transverse vertical plates which can be screwed down so as to regulate the thickness of the stream of solution, and with a discharging weir.—L. F. G.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

Alcoholic Potash Solution; Preparation of a Stable ——. Thiele and R. Marc. Z. öfentl. Chem., 1904, 10, 36—387. Chem. Centr., 1904, 2, 1756.

40 grms. of pure potassium sulphate are well mixed with 120 grms. of barium hydroxide in a platinum or porcelain dish, 100 c.c. of water are added, and the whole weighed. The contents of the dish are then boiled for 15 minutes, with continuous stirring, and after cooling, water is added to make up the original weight. The solution is then rinsed into a bottle with 800 c.c. of alcohol, rather 100 c.c. of water is added, the bottle is closed and well shaken, 3-4 c.c. of a concentrated solution of potassium sulphate are added to ensure the complete precipitation of the baryta, and the whole is again well shaken, and allowed to settle. It is stated that the clear supernatant liquid will remain clear and colourless for six months.—A. S.

Acid Compounds of Organic Bases. L. Spiegel and L. Spiegel. Ber. deutsch. pharm. Ges., 1904, 14, 350—355. Chem. Centr., 1904, 2, 1611.

ANILINE borate can be prepared by heating equimolecular amounts of aniline and of boric acid with absolute alcohol (ether, or by boiling finely-powdered boric acid with excess of aniline for a long time. Solid aniline borate is obtained on washing the product of the reaction with water; it is decomposed into its components by water. Boric acid compounds of piperidine, coniine, and tetrahydroquinoline are precipitated on mixing together ethereal solutions of boric acid and of the base. On adding two molecular proportions of boric acid to an aqueous solution of one molecular proportion of tetramethylammonium hydroxide, concentrating the solution to a syrup, and treating the residue with absolute alcohol, a crystalline mass separates.—A. S.

Aldehydes; New Synthetic Preparation of ——. L. Bouveault. Bull. Soc. Chim., 1904, 31, 1322—1327.

THE magnesium-alkyl or magnesium-aryl halide ("Grignard's reagent") is first prepared, and into that is actually dropped an ethereal solution of a mono- or substituted formamide or formanilide; the reaction is usually violent, and cooling must be resorted to. With one of the higher alkyl chlorides the formation of the magnesium compound is only complete after adding benzene and heating; but the mixture must then be cooled before adding the formamide. The product of the reaction is treated with water, and made just acid by gradually adding sulphuric acid (avoiding rise of temperature). The ethereal layer fractionally distilled, yields an aldehyde mingled with some of the original halide, from which it is purified by means of the bisulphite reaction. The aqueous layer, rendered alkaline and distilled regenerates the amine from which the formamide was originally prepared. The general reaction (using methylformamide) is expressed by

The substituted formamides are readily prepared, and with

good yields, by heating together acid and base, piperidylformamide at once, by simple distillation, diethylformamide after fractionating and distilling from quicklime. The dimethyl compound is less advantageous.

The author has thus prepared and examined valeric, isobutylic, nonylic (colourless, strong-smelling, boiling at 81° C. under 14 mm.), decylic (similar, b.p. 91° C. under 11 mm.), and, in very small quantities, trimethylacetic and ethyldimethylacetic aldehydes; also hexahydrobenzoic, benzoic, phenylacetic, and hydrocinnamic aldehydes.—J. T. D.

Iodoform; Decomposition of —, by the Combined Action of Light and Oxygen. E. van Aubel. Phys. Zeits., 1904, 5, 637. Science Abstracts, 1904, 7, A, 987—988.

It has been previously shown by Hardy and Willcock, that in presence of oxygen, iodine is liberated from solutions of iodoform by the action of light, of Röntgen rays, or of radium emanations. The author finds that under similar conditions, iodine is also liberated from the iodoform contained in a non-fluid mixture (e.g., iodoform and vaseline). A solution of iodoform in chloroform is not appreciably decomposed by winter sunlight, if the temperature of the solution be kept at -45° C.—A. S.

Eucalyptus Oil; Adulterated ——. C. T. Bennett. Chem. and Drug., 1905, 66, 33—34.

It is stated that for some time past large consignments of eucalyptus oil, adulterated with castor oil, have been sold. The oil answers the characters and tests of the B. P., but has a rather high viscosity, and contains less cineol than is consistent with its sp. gr. Samples of the adulterated oil had sp. gr. 0.917—0.919, and optical rotation 0° to +2°, and contained from 38 to 45 per cent. of cineol. On fractional distillation under reduced pressure, a residue was left, agreeing in character with castor oil. One sample of the adulterated oil contained nearly 20 per cent. of castor oil, and others, from 12 to 15 per cent.—A. S.

Antipyrine; Volumetric Determination of ——. P. Lemaire. XXIII., page 109.

Lemon Oil; Determination of the Saponification Value and the Dry Residue of ——. E. Berté. XXIII., page 108.

ENGLISH PATENT.

Tannin-like Substances and Urea; Process for Manufacturing Condensation Products from —, by means of Formaldehyde. R. Lanch and A. Voswinkel, Berlin. Eng. Pat. 23,569, Nov. 1, 1904.

TANNIN-LIKE substances may be condensed with urea and formaldehyde in aqueous solution, or in presence of a condensing agent, to form "methylene tannin ureas;" that obtained from tannin has the constitution $\text{C}_{14}\text{H}_{10}\text{O}_6\text{CH}_2\text{NH.CO.NH}_2$. These substances are soluble in alkalis, and reprecipitated by acid. Tanning agents other than tannin (e.g., rhatania tannic acid) give similar products, as do also the substitution derivatives of tannin. Monobromotannin gives a monobromoderivative soluble in alkali carbonates and borates, and sparingly soluble in alcohol. All these substances possess astringent properties, the bromoderivatives also possessing anti-septic properties.—T. F. B.

UNITED STATES PATENTS.

Halogen Tertiary Butyl Alcohol; Process of Making ——. T. B. Aldrich and C. P. Beckwith, Detroit, Mich. U.S. Pat. 777,712, Dec. 20, 1904.

A mixture of a halogen substitution product [of a ketone] with a considerable excess of ketone is caused to flow upwards through a rotating broken mass of "condensing agent," the temperature of the mixture introduced and of the reaction vessel being maintained at or below 0° C. The product is then neutralised, and the excess of uncombined ketone distilled off from the halogenated tertiary butyl alcohol. The distilled ketone is then mixed with more halogenated ketone, and the mixture again subjected to condensation, further amounts of ketone being added when the reaction becomes too vigorous. (Compare U.S. Pat. 761,188 of 1904; this J., 1904, 726.)—T. F. B.

ology Compound (p-Iodoxyphenol Ester); and Process of Making same. A. Liebrecht, Frankfurt, Assignor to Farbwerke vorm. Meister, Lucius und Brünig, Höchst-on-the-Maine, Germany. U.S. Pat. 777,962, Dec. 20, 1904.

PARA-IODOXYPHENOL esters are converted by oxidation into the corresponding *p*-iodo-oxyphenol esters, which are generally soluble with difficulty in cold water, more easily in hot water, easily soluble in acetic or formic acid, and insoluble in alcohol or ether; *p*-iodo-oxyanisole, $\text{CH}_3\text{O} \cdot \text{C}_6\text{H}_4 \cdot \text{O} \cdot \text{I}$, obtained by oxidising iodo-anisole, melts, with simultaneous combustion, at about $225^\circ \text{C} = \text{T. F. P.}$

XXI. — PHOTOGRAPHIC MATERIALS AND PROCESSES.

Metals. Action of — on the Photographic Plate. G. W. A. Kahlbaum, Naturforsch. Ges., Basel. *Through Brit. J. Phot.*, 1904, 51, 1108—1109.

Pieces of aluminium, iron, zinc and lead were separated from two photographic plates, one placed above and the other below them, by a piece of cardboard and a sheet of waxed paper. The film of the upper plate was turned away from the metal. The whole was kept in a dark room for five days. Upon development, well defined and strong images of the four metals were found upon the lower plate, whilst the upper plate indicated a very faint image from the aluminium, and a slightly stronger one from the zinc. On exposing the metals between the two plates held vertically, the action was found to be similar on each plate, but weak, whilst when a strip of lead was placed diagonally between the two plates, a weak image, distorted into parabolic form, was produced. The intensity of the images produced appeared to vary inversely with the distance of the metal from the plate. The emanations thus appear to be influenced by gravity, and to traverse glass. The temperature and humidity of the air appear to have a considerable effect on this action, which has also been observed with copper, nickel and uranium. —T. F. B.

Photographic Development; A Method of —, which permits the Production of Fine Grained Images. Lumière and Seewetz. *Bull. Soc. franc. de Phot.*, 1904, 422; *Chem.-Zeit.*, 1904, 28, Rep. 380.

THE conditions necessary for the production of finely-grained images are slow development (obtained by using retarding agents or dilute solutions) and the presence of a body capable of dissolving silver bromide; too large an amount of this must not be used, however, as otherwise silver bromide would be dissolved before the image was developed. Ammonium chloride (15 to 20 grms. for 100 c.c. of developer) is recommended for this purpose. *p*-Phenylenediamine and *o*-aminophenol also yield finely-grained images because they possess only slight reducing power, and are also able to dissolve silver bromide. The following is a good developer: Water, 1000 c.c.; *p*-phenylenediamine, 10 grms.; anhydrous sodium sulphate, 60 grms.

According to Lüppo-Cramer (*Phot. Korr.*, 1904, 41, 512) the above process is a purely physical one, as can be proved by the fact that a primarily fixed negative placed in the same bath is developed by the silver chloride or bromide dissolved from the unfixed plates. Highly sensitive plates require a longer exposure if treated in this way, and yield a strong dichroic fog. The solvent action of ammonium chloride on silver bromide is ascribed to the action of ammonia produced by the alkali of the developer; when ferrous oxalate developer is used it has no action. —A. G. L.

ENGLISH PATENT.

Colour Photography; Sensitised Plates for a Process of —. La Soc. Anon. des Plaques et Papiers Photographiques A. Lumière et ses fils, Lyon-Monplaisir, France. Eng. Pat. 22,988, Oct. 25, 1904. Under Internat. Conv., Dec. 17, 1903.

A SHEET of glass is coated with a suitable adhesive, and a layer of coloured, transparent grains is applied to it. The grains may be of starch, enamels, &c., and the colour used should also be transparent; three equal masses of the grains are coloured respectively red, yellow, and blue, and are mixed as intimately as possible. The layer of grains should be so applied that the grains touch each other without being superimposed. This layer is covered with a second adhesive coating, a second layer of coloured grains applied, and the whole covered with varnish; the sensitive film is then applied to the prepared plate in the usual way. The varnish and the adhesive should have approximately the same refractive index as the transparent grains, in order that the light may not be deflected or diffused. The plate is exposed in the camera with its glass side to the lens, and is finished in the usual way, and "reversed"; on viewing the finished plate by transmitted light, a reproduction in colours of the original is obtained. —T. F. B.

XXII. — EXPLOSIVES, MATCHES, Etc.

Freezing of Nitroglycerin and Nitroglycerin Explosives. Study of the Conditions of —. S. Nauckhoff. *Z. angew. Chem.*, 1905, 18, 11—22; 53—60.

MANY attempts have been made to prepare nitroglycerin explosives capable of withstanding comparatively low temperatures without freezing, but no satisfactory solution of the problem has yet been worked out. At the present time nitrobenzene, nitrotoluene, &c., are added to the nitroglycerin, but it has not been found possible to depress the freezing-point of the explosive considerably below 0°C , without at the same time greatly reducing its explosive power. As a contribution to the solution of the problem, the author gives the results of an investigation of the freezing of nitroglycerin, and of the lowering of its freezing-point by additions of various substances. Pure nitroglycerin can be cooled to temperatures (-40° to 50°C) much below its true freezing-point, without becoming solid. When cooled by means of a mixture of solid carbon dioxide and ether, it sets to a glassy mass, without any perceptible crystallisation. The mass when warmed to 0°C . first rapidly liquefies and then begins to crystallise. The true freezing-point of pure nitroglycerin was found to be 12.3°C ; the technical product, owing to the presence of dinitroglycerin, freezes at 10.5°C .

According to Raoult's law, the lowering of the freezing-point caused by m grms. of a substance with the molecular weight M , when dissolved in 100 grms. of the solvent, is expressed by the formula: $\Delta = E \cdot \frac{m}{M}$, where E is a constant characteristic for the solvent in question. The value of E for nitroglycerin was found to be 70.5 when calculated, according to van t'Hoff's formula, from the melting-point and the latent heat of fusion of the substance. Determinations of the lowering of the freezing-point of nitroglycerin by additions of benzene, nitrobenzene, dinitrobenzene, trinitrobenzene, *p*-nitrotoluene, *o*-nitrotoluene, dinitrotoluene, naphthalene, nitronaphthalene, dinitronaphthalene, ethyl acetate, ethyl nitrate, and methyl alcohol, gave results agreeing fairly well with Raoult's formula except in the case of methyl alcohol, for which the calculated lowering of the freezing-point was greater than that observed, probably owing to the formation of complex molecules in the solution. The results show that, in general, the capacity of a substance to lower the freezing-point of nitroglycerin depends not

its freezing-point, or its chemical composition, but upon its molecular weight. Experiments with a number of samples of dynamite, including technical products and specimens specially prepared, gave results showing that by the aid of Raoult's rule, the freezing-point of a nitroglycerin explosive can be calculated with sufficient accuracy for practical purposes from its composition. The resistance of a nitroglycerin explosive to cold depends, however, not only upon its freezing-point, but also upon its power of undergoing cooling below its freezing-point without solidifying. The author has found that the more plastic the explosive is, the better it resists this supercooling. The plasticity of a dynamite depends not only upon the amount of nitrocellulose contained in it, but also upon the ready solubility and gelatinising properties of the same. A cartridge of dynamite freezes more rapidly than a lead one; also the explosive does not freeze so easily at a very low temperature as at one only a few degrees above the true freezing-point. A specimen of dynamite which has been frozen and then thawed does not resist recooling so well as one that has not been frozen. In conclusion, the author states that a suitable substance dissolving in nitroglycerin in order to lower the freezing-point of the latter, must have a relatively low molecular weight, must not appreciably diminish the explosive power and stability of the explosive, and must be easily volatile at relatively high atmospheric temperatures; it should, if possible, be a solvent of nitrocellulose, and, in any case, must not have a prejudicial effect on the gelatinisation of the nitrocellulose. (See this J., 1904, 680).—A. S.

Calcium Carbide as an Explosive in Mines. M. P. S. Juedras. *Comptes rend.*, 1904, **139**, 1225—1226.

Calcium carbide is introduced into a metallic cartridge, separated by a diaphragm from the necessary water for its decomposition; the cartridge also contains an air-space or a cavity containing a detonator. The cartridge is introduced into the borehole, which is tamped with a wooden plug, and by striking a projecting rod the diaphragm is pierced. After 5 minutes the cartridge is exploded by firing the detonator. The rock is shattered, but not projected, and can be easily hewn with the pick. The charge of carbide is 50 grms.—J. T. D.

ENGLISH PATENTS.

Blasting Compounds. A. F. Hargreaves, Roslin, Scotland, and Curtis's and Harvey, Ltd., London. Eng. Pat. 4028, Feb. 17, 1904.

Potassium chlorate (78 parts) is mixed with dinitrotoluene (22 parts). To 75 parts of this mixture are added 25 parts of blasting gelatin (nitroglycerin 90 per cent., collodion 10 per cent.). The addition of wood-meal (3 per cent.) improves the keeping qualities of the explosive. The resulting explosive is plastic and can be pressed into cartridges. It is claimed that the blasting gelatin is thus employed as a colloid vehicle for holding the particles of chlorate, protecting them from water and abrasive agents, reducing their sensitiveness and rendering the blasting compound safe.—G. W. McD.

Blasting Compounds. A. F. Hargreaves, Roslin, Scotland, and Curtis's and Harvey, Ltd., London. Eng. Pat. 4028, March 16, 1904.

Potassium chlorate (78 per cent.) is mixed with dinitrotoluene (22 per cent.). To 75 parts of this mixture are added 25 parts of blasting gelatin (nitroglycerin 90 per cent., collodion 10 per cent.). The resulting explosive is plastic and can be pressed into cartridges. Wood-meal (3 per cent.) may also be added to improve the keeping qualities of the explosive and sodium, ammonium and potassium perchlorates can be used in place of sodium chlorate. (See also Eng. Pat. 4028 above).—G. W. McD.

Explosives; Manufacture of —. C. Duttenhofer, Hamburg, Germany. Eng. Pat. 24,782, Nov. 15, 1904. In order to prevent muzzle flame on firing a shot, an alkali carbonate is added to the explosive. It is said to have

no detrimental effect on the stability of the explosive, as is the case with the normal carbonate. An example given is nitrocellulose (75 parts), nitroglycerin (25 parts), vaseline (5 parts), sodium bicarbonate (2 parts).

—G. W. McD.

FRENCH PATENTS.

Heat [Firing Explosives]; Means for Producing —, by Chemical Reaction. L. Partl, G. Károlyi, and E. Paatz. Fr. Pat. 345,751, Aug. 22, 1904.

A composition which, on addition of water or of a dilute acid, will give out heat available for firing explosive bomb-shells, or which may itself be used to charge projectiles, is formed by mixing quicklime with one or more of the following substances, in proportions suited to the circumstances:—potassium carbonate, chlorate, chloride, or nitrate; sodium phosphate, nitrate, or chloride; magnesium carbonate; calcium phosphate or chloride; lead carbonate; and sugar. —E. S.

Explosive Compound; Method of Manufacture of —. H. Boyd. Fr. Pat. 346,135, Sept. 8, 1904.

The composition consists of sodium nitrate (35 per cent.), rosin (10 per cent.), naphthalene (10 per cent.), petroleum shale (15 per cent.), sulphur (10 per cent.), other ingredients (20 per cent.). It is claimed that the sodium nitrate is thus rendered non-hygroscopic. The three first ingredients are kneaded together with addition of petroleum, the other ingredients being added subsequently, the resulting explosive being either granulated or compressed into cartridges as required.—G. W. McD.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS, ETC.

Sodium Borates; Some Physical Characters of the —, with a New and Rapid Method for the Determination of Melting Points. C. H. Burgess and A. Holt, Jun. VII., page 88.

UNITED STATES PATENT.

Cupel. J. C. Fox, Assignor to The Morgan Crucible Co., Ltd., London. U.S. Pat. 777,725, Dec. 20, 1904.

INORGANIC—QUALITATIVE.

Perchlorate; Sodium Nitrate containing — [Detection of Chlorates]. H. Pellet and G. Fribourg. XV., page 98.

INORGANIC—QUANTITATIVE.

Ammonium Chloride; Dissociation of —, regarded from the Analytical Standpoint. L. Santi. *Boll. Chim. Farm.*, 1904, **43**, 673—681. *Chem. Centr.*, 1904, **2**, 1625—1626.

Iron, in the form of cuttings, is readily attacked by a warm, concentrated solution of ammonium chloride, with evolution of hydrogen and ammonia, whilst magnesium powder is attacked even in the cold; a soluble, double chloride is formed in each case, $\text{FeCl}_2 \cdot 2\text{NH}_4\text{Cl}$ and $\text{MgCl}_2 \cdot 2\text{NH}_4\text{Cl}$, respectively. Cadmium, zinc, chromium, manganese, and tin are also more or less readily attacked by ammonium chloride solution. Most metallic oxides are converted into the corresponding chlorides by heating with dry ammonium chloride, but nickel and cobalt oxides are reduced to the corresponding metals. Nickel oxide, manganese protoxide and ferrous oxide, as also calcium, magnesium, copper, cobalt and nickel carbonates are converted into the corresponding chlorides by ammonium chloride solution; sesquioxides are not acted upon. Tin and antimony sulphides are attacked by dry ammonium chloride, whilst manganese sulphide, and, less readily,

zinc sulphide are acted upon by ammonium chloride solution. Thiosulphates when boiled with excess of ammonium chloride solution, are decomposed according to the equation: $\text{Na}_2\text{S}_2\text{O}_3 + 2\text{NH}_4\text{Cl} = 2\text{NaCl} + 2\text{NH}_3 + \text{H}_2\text{O} + \text{SO}_2 + \text{S}$. Manganites are converted into permanganates in the cold by ammonium chloride; and chromates into bichromates, chromic acid being finally liberated from the latter. The reaction of barium peroxide with hot ammonium chloride solution affords a means of obtaining a regular supply of oxygen for laboratory purposes: $\text{BaO}_2 + 2\text{NH}_4\text{Cl} = \text{BaCl}_2 + 2\text{NH}_3 + \text{H}_2\text{O} + \text{O}$. Potassium persulphate when boiled with ammonium chloride solution, yields chlorine and nitrogen, whilst on distilling the reaction-products, hypochlorous acid can be detected.—A. S.

Sulphuric Acid: Determination of —, by Benzidine Hydrochloride. Determination of Sulphur in Pyrites. G. v. Knorre. Chem. Ind., 1905, 28, 2—13.

As a member of Sub-Committee IX. of the International Committee on Analysis, the author has examined the relative merits of Lunge's and Silberberger's methods of determining sulphur in pyrites. He concludes that Lunge's method (Taschenb. Sodafabr., 3rd Edit. 140), properly carried out, gives accurate results; and that though Silberberger's method (this J., 1903, 1149) may also give accurate results, yet it has many faults—the filtrates are turbid, the filtration very slow, the strontium sulphate contains considerable quantities of iron, the strontium sulphide formed during incineration of the filter re-oxidises very slowly, so that constancy of weight is long in being attained, and the large consumption of alcohol makes the process costly.

He has examined also the benzidine method of determining sulphates, as developed by Raschig (this J., 1903, 1066), confirming Raschig's results, and finds no difficulty in following his directions. In titrating, he usually heats the magma of water, benzidine sulphate, and filter paper to 60°—100° C., adds a drop of phenolphthalein and a distinct excess of N_{10} sodium hydroxide solution and heats to boiling, to ensure complete decomposition of the benzidine sulphate. He then acidifies with N_{10} hydrochloric acid, boils to expel any carbon dioxide, and titrates with the soda solution. In this way he has found that sulphuric acid can be accurately determined in presence of ferrous, cupric, nickel, cobalt, manganese, zinc, chromium, or aluminium salts, but that ferric salts react on the benzidine, forming oxidation products which render the method useless. Ferric sulphate acts less energetically than ferric chloride, but even in this case the removal or reduction of the iron is necessary, or no confidence can be placed in the results. The author confirms Raschig's statement that hydrazine hydrochloride can be used as a reducer; but he also finds that hydrogen sulphide acts satisfactorily in the same capacity. He has proved that no sulphuric acid is formed from the hydrogen sulphide, even when nitric acid is present in the solution, and he works as follows:—The cold iron solution is poured into a quantity of hydrogen sulphide water containing roughly double the amount needed for the reduction of the iron (100 c.c. of saturated solution at 15°—17° C. contain about 0.44 gm. of hydrogen sulphide), and after mixture, the liquid is heated till it ceases to smell of the gas. The liquid is made up to a known volume, filtered through a dry filter, and an aliquot part taken for the precipitation. Hydroxylamine was found by Raschig to be unsuitable as a reducer; the author finds that the acid formed during the reaction of the hydroxylamine is responsible for this, and that hydroxylamine can be used if the solution be rendered just alkaline by ammonia, so that a small permanent precipitate is formed, which goes completely into solution during the reduction. In the case of small amounts of ferric salt, such as are present in the analysis of pyrites, the addition of 0.5 gm. of hydroxylamine hydrochloride, though it may not completely reduce the iron, is enough to prevent it from reacting on the benzidine.

This method can be advantageously applied to pyrites; when it is used, the evaporation to dryness is not necessary, but the solution of the pyrites (according to Lunge's directions) is diluted with water, nearly neutralised with

ammonia, and made up to 250 c.c., of which 50 c.c. are used for a determination. The iron may be reduced by 10 c.c. of hydrogen sulphide water, and after expulsion of excess of the gas and cooling, the solution is poured into 320 c.c. of the benzidine solution; or in the benzidine solution there may be dissolved 0.5 gm. of hydroxylamine hydrochloride, and the solution of the pyrites is poured into this without reducing the iron. Or the solution, diluted with water, may be treated with excess of ammonia and digested for 10 minutes at 60°—70° C., then cooled and diluted to 250 c.c., filtered through a dry filter, and 50 c.c. taken for the benzidine precipitation (making it very slightly acid before precipitating). As no evaporation is needed, this method is exceedingly rapid. In using it for copper pyrites or other sulphides for the complete oxidation and solution of which large quantities of acid are needed, however, the evaporation of most of the excess of acid cannot be dispensed with; for otherwise the large amounts of alkaline salts formed in nearly neutralising the acid hinder the complete precipitation of the benzidine sulphate.

—J. T. D.

Manganese: Determination of — as the Green Sulphide. J. C. Olsen, E. S. Clowes and W. O. Weidmann. J. Amer. Chem. Soc., 1904, 26, 1622—1627. (See page 89).

For 150 mgrms. of manganese, 10 c.c. of a 5-N solution of ammonium chloride or 2.75 grms. of the dry salt, and five times the theoretical amount of ammonium sulphide are used. The concentrated solution of the manganese salt (10 c.c.) is poured into the boiling solution of the ammonium salts (90 c.c.), and the heating continued until the pink sulphide which is first precipitated is completely transformed into the green modification. The ammonium sulphide must be prepared immediately before use, be free from the yellow sulphide, and must be used in sufficient excess. The transformation of the pink precipitate into the green sulphide is generally complete in half an hour; if necessary 10 or 15 c.c. more of the ammonium sulphide solution are added after this time. The green sulphide is filtered off, washed with distilled water containing ammonium sulphide and chloride, dried and ignited in a current of dry hydrogen free from arsenic hydride.

—A. S.

Chromium in Steel; Note on the Determination of —. F. Ibbotson and R. Howden. Chem. News, 1905, 51, 3.

Chromium salts in nitric acid solution are completely oxidised to chromic acid by sodium bismuthate, but the oxidation proceeds so slowly in the cold that the presence of chromium does not interfere to any appreciable extent with the determination of manganese by Reddrop and Ramage's bismuthate method (this J., 1895, 305). For the determination of manganese and chromium in one and the same sample of steel, the manganese is determined as previously described (*loc. cit.*), and after titrating the permanganate, 50 c.c. of nitric acid of sp. gr. 1.2 and 10 grms. of sodium bismuthate are added, and the mixture is heated to boiling. When the oxidation of the chromium is complete, with production of a clear, red solution, a pinch of manganous sulphate is added, and the boiling is continued for a minute or two to decompose the permanganate formed. The small quantity of precipitated manganic oxide is filtered off, and the chromic acid in the filtrate is determined in the usual manner by means of ferrous sulphate and potassium permanganate.—A. S.

Sulphur [In Iron]: The Wiborgh Test for —, using a Filter. Ax. Silverling, Jern-Kontorets Annaler, 1904, 59, 114; Chem.-Zeit., 1904, 28, Rep., 368.

GRABE (Teknisk. Tidskrift., 1902, 32, 89) modified Wiborgh's method (Chem. News, 54, 158) by boiling the solution for a shorter time, but more vigorously. The author finds that by inserting a filter some little distance below the piece of cotton, which is soaked in cadmium acetate solution, any spray is caught, and the colours obtained are, in consequence, pure yellow without any brownish tinge.—A. G. L.

Lead and Antimony: Determination of —, as Sulphides. J. A. Muller. Bull. Soc. Chim., 1904, 31, 1300—1303.

THE warm solutions (35° C.), that of lead acidified with

1 per cent. of nitric acid, that of antimony containing excess of hydrochloric acid and some tartaric acid, are made up with water to 300–500 c.c., and saturated with hydrogen sulphide. The precipitates are filtered off through tared filters, washed successively with water containing hydrogen sulphide, 95 per cent. alcohol, a mixture in equal volumes of 95 per cent. alcohol, ether, and carbon bisulphide, and finally with absolute ether; they are then dried *in vacuo* over sulphuric acid, and weighed. The filters are previously treated in pairs with the same solvents, dried, and one balanced against the other, the small difference in weight being determined and recorded; when weighing the precipitate, the second filter is again used as a counterpoise for the other. Trial determinations with lead nitrate, in quantities varying from 0.25 to 2.0 grms. of sulphide, gave from 99.7 to 100.1 per cent. of the actual amount of lead. Similar determinations with antimony sulphide gave from 99.8 to 100.6 per cent. of the actual amount of antimony.—J. T. D.

Lead Ores; Complete Analysis of ——. J. A. Muller. Bull. Soc. Chim., 1904, 31, 1303–1306.

5 gm. of the finely-powdered ore is treated in a covered platinum capsule, with 10 c.c. of nitric acid of sp. gr. 1.33, added gradually, and kept warm for 12 hours. Extraction is effected with warm water, decanting through a small filter. To the filtrate 40 c.c. of 10 per cent. sodium acetate solution are added, the liquid boiled, filtering from any precipitated iron, and in the filtrate the silver is determined as chloride. The residue in the capsule is now treated with 60 c.c. of a mixture of equal volumes of fuming hydrochloric acid and water, and to this the solution, in hydrochloric acid, of the basic ferric acetate precipitate is added. After filtering and washing the filtrate is added to the filtrate from the silver precipitate, the insoluble residue silica and barium sulphate are determined in the usual way. The combined filtrates (containing all the soluble constituents of the ore except the silver) are made up to 1½ litres, heated to 70° C., saturated with hydrogen sulphide, allowed to stand for a day, and filtered through a tared filter. After washing, the precipitate is detached as far as possible from the filter, and treated with 6 c.c. of concentrated yellow ammonium sulphide solution (or sodium sulphide in presence of copper) nearly at boiling temperature; after decanting through the filter, and washing three or four times with small quantities of hot water containing 0.5 c.c. of the yellow sulphide, the precipitate is rinsed on to the filter and washed there with pure water. The receiver is changed, and the washing continued first with alcohol, then with a mixture of alcohol, ether and carbon bisulphide, and finally with ether; the washed precipitate is dried *in vacuo* (see preceding abstract). Copper and silver must be looked for in aliquot parts of this precipitate, and, if found, determined. The ammonium sulphide solution contains arsenic and antimony; it is acidulated with hydrochloric acid, the solution filtered, the precipitate washed with water, alcohol, &c., as above, and dried. After boiling with 1 c.c. of a mixture of 2 vols. of fuming hydrochloric acid and 1 vol. of water, the liquid is filtered. The insoluble arsenic sulphide is next oxidised by means of nitric acid, and the arsenic determined as ammonium magnesium arsenate, examining the filtrates for arsenic and antimony, and determining any small amounts found. The solution of the antimony is diluted to a litre, and antimony determined as sulphide (see preceding abstract). In the filtrate from the hydrogen sulphide precipitate, iron, zinc, calcium, &c., are determined.—J. T. D.

Metals; Electrolytic Deposition of ——. *with Rapid Stirring of the Electrolyte*. A. Fischer and R. J. Boddaert. Z. Elektrochem., 1904, 10, 945–953.

THE authors retain as closely as possible the Classen methods, employing a dish of platinum or other metal, as cathode, and a platinum disc or spiral as anode (with lead, *vice versa*). The stirring is effected by a rapid rotation of the anode. In nearly all the cases investigated a very marked acceleration of the deposition is possible, in some cases it was found advantageous to employ other electrolytes than those in general use for the electrolytic termination of metals. The following table shows the

time required for the complete deposition of 0.2 to 0.4 grm. of metal:—

Metal.	Time required without stirring A (Hours)	Time required with stirring B (Minutes)	Ratio A : B.
Nickel	3	40	4.5 : 1
Zinc	2	15	8 : 1
Copper	6	20	18 : 1
Cadmium	3	10	18 : 1
Lead	1	15	4 : 1
Silver	3	15	12 : 1
Mercury	1½	15	10 : 1
Antimony	1½	30	4 : 1
Tin	6	20	18 : 1

A special stand to hold both anode and cathode has been devised by the author.—R. S. H.

Rotating Anode in Electro-Analysis; Use of the ——. E. F. Smith, G. H. West and L. G. Kollock. J. Amer. Chem. Soc., 1904, 26, 1595–1615.

THE results are given in the form of tables and curve-diagrams of the determination of nickel and cobalt, and the separation of cobalt from the alkaline-earth metals. In all the experiments the volume of the electrolyte ranged from 100 to 125 c.c., representing a cathode surface of 100 sq. cm., whilst the anode was rotated at from 500 to 650 revolutions per minute. Satisfactory results were obtained with electrolytes of ammonium acetate, sodium acetate, ammonia and ammonium sulphate, ammonium formate, sodium formate, and ammonium lactate in the determination of nickel; with sodium formate, ammonium formate, ammonium acetate, sodium lactate, ammonium lactate, and ammonium succinate in the determination of cobalt; and with formate electrolytes in the separation of cobalt from calcium, strontium, barium and magnesium.

Some experiments with a rotating anode and mercury cathode indicate that under suitable conditions, it will be possible to deposit 0.5 gm. of copper and 0.25–0.5 gm. of nickel in 15 minutes. (See also this J., 1903, 1150; 1904, 1114, 1115.)—A. S.

Sodium Borates; Some Physical Characters of the ——. *with a New and Rapid Method for the Determination of Melting Points*. C. H. Burgess and A. Holt, Jun. VII., page 88.

ORGANIC—QUALITATIVE.

Wood-Tar Pitch; Behaviour of ——. *with Certain Organic Solvents*. B. M. Margosches. Chem. Rev. Fett-u. Harz-Ind., 1905, 12, 5–9.

THIS is an extension of the investigation begun by Donath and the author (this J., 1904, 541). The samples of beech wood-tar pitch used in the experiments had the following elementary composition: Bosnian pitch, carbon, 63.0, and hydrogen, 6.0 per cent.; Hungarian pitch, carbon, 66.0, and hydrogen, 10.0 per cent. The amount of oxygen in wood-tar pitch is thus much greater than in other artificial "asphalts." In testing their behaviour with the different solvents, about 0.1 to 0.3 gm. was treated with about 10 to 15 c.c. of the liquid. In the case of carbon tetrachloride the solvent acquired a faint yellow tinge after about 24 hours, whilst at 39° C. the yellow coloration was more pronounced. Carbon bisulphide remained colourless for some minutes, and then acquired a faint yellow coloration, which reached its maximum intensity after about 15 minutes, and did not darken perceptibly after standing for 24 hours at the ordinary temperature or at 30° C. This test, therefore, affords another means of distinguishing between wood-tar pitch and other artificial "asphalts." A still more characteristic test was given by petroleum spirit, which remained absolutely colourless after standing for 24 hours in contact with the pitch, although it dissolved about 2 per cent. of the samples. Experiments with other petroleum solvents (benzene and ligroin) gave the same results. In 1884 Davies (Chem. and Druggist, 25, 504), found that wood-tar pitch was much more soluble

in petroleum spirit (16.0 to 24.4 per cent.), and the author accounts for this by the fact that at that time, a smaller amount of tar oils was expelled from the pitch during the distillation. The pitches examined by the author were derived from wood-tars that had been distilled at about 270° C. A specimen of crude Bosnian tar was found to be slightly soluble in petroleum spirit (yellow coloration), and considerably soluble in ligroin (reddish-yellow coloration). Chloroform had the greatest solvent action on wood-tar pitch of any of the solvents tried, a dark brown solution being obtained. Alcohol dissolved only a small amount, the liquid becoming yellow after some time. Ether behaved in the same way, though its solvent action was somewhat greater. The two samples behaved differently with benzene. The Hungarian wood-tar pitch did not impart any coloration to the solvent for a long time, and after 12 hours the liquid had only a faint yellow tint. On the other hand the benzene, when shaken with the Bosnian pitch, became yellow in about 5 minutes, the colour changing to reddish-yellow after 30 minutes, and to red after about 12 hours. Successive extraction of this sample with petroleum spirit, benzene and carbon bisulphide showed that those portions that were soluble in carbon bisulphide were for the most part insoluble in benzene and petroleum spirit. — C. A. M.

Sesame Oil; Detection of — in the presence of Colouring Matters that give a Red Coloration with Hydrochloric Acid. G. Fendler. Chem. Rev. Fett- u. Harz-Ind., 1905, 12, 10—11.

BEING unable to identify sesame oil by Baudouin's test in a fat containing a colouring matter of the character described in the title, the author had recourse to Soltien's test (this J., 1903, 1017), which was applied in the following manner:—The fat was mixed with twice its volume of benzene and half its volume of the stannous chloride solution, and the test tube placed in a water-bath at about 40° C., until the stannous chloride solution separated. The tube was then placed in water at 80° C., but so that the level of the water outside was not above that of the stannous chloride layer, and heated until the red coloration in that layer no longer increased. When sesame oil was not present, the coloration caused by the colouring matter in question soon disappeared, and the stannous chloride solution remained colourless after further heating. — C. A. M.

Oil of Turpentine; Examination of —. H. Herzfeld. Z. öfentl. Chem., 1904, 10, 382—384. Chem. Centr., 1904, 2, 1770.

THE oil obtained by the distillation of resinous wood has, within recent time, been refined to such a degree, that now neither odour, nor colour reaction with caustic soda and concentrated hydrochloric acid, can, as heretofore, be used for distinguishing it. This refined oil, however, when shaken with an equal volume of sulphurous acid solution, is coloured yellowish-green, and can be detected in this way, when present to the extent of 10 per cent. in oil of turpentine. — A. S.

Rosin and Fish Oils; Detection of —, in Boiled Linseed Oil. W. Lippert. Chem. Rev. Fett- u. Harz-Ind., 1905, 12, 4—5.

THE author's experiments to determine the value of the Storch-Morawski reaction for rosin and fish oil have shown that varnishes prepared by the old method of boiling linseed oil with lead or manganese oxides yield products which give only brown colorations in the test; whilst on the other hand, red or blue colorations are obtained when resins have been used, or when rosin oil or fish oils are present. Attention is called to the fact that maize oil gives a similar reaction. Samples of boiled linseed oil, adulterated with sardine oil, &c., examined by the author, gave the Storch-Morawski and other reactions for fish oil. After exposure to the light, however, the reactions given by the oil became fainter, and eventually, after a year, no colour reactions could be obtained. It was still possible to detect the adulteration by separating the cetyl alcohol (m. pt. 50° C.), and by other reactions. The kind of fish oil was not identified,

and various fish oils tried did not give the Storch reaction. The author's general conclusion is that the test should not be omitted in a qualitative examination of boiled linseed oil, although it is not a conclusive sign of purity when no coloration is obtained. — C. A. M.

Saccharin in Wine; Qualitative Detection of —. E. MacKay Chace. J. Amer. Chem. Soc., 1904, 26, 1627—1630.

MANY wines, especially French wines of the santerne type, contain a substance or substances giving the salicylic acid test for saccharin, salicylic acid being actually formed from them on fusion with sodium hydrate. Permanganate is moreover ineffectual in the cold, in destroying salicylic acid. The following method is recommended:—50 c.c. of the wine are extracted with ether, and the extract, after evaporation of the ether, re-extracted with petroleum spirit (gasoline). The petroleum extract is tested for salicylic acid, then added to the portion of the ether extract insoluble in petroleum, the whole made up to 10 c.c., 1 c.c. of sulphuric acid (1 in 3) added, and the solution heated to boiling. An excess of a 5 per cent. solution of potassium permanganate is now added, and if salicylic acid be present, the boiling is continued for 1 minute. A small piece of sodium hydroxide is then added to the hot liquid, and after a few minutes, the alkaline solution is filtered, evaporated to dryness, and the residue heated to 210°—215° C. for 20 minutes. It is then dissolved in water, the solution acidified with sulphuric acid, extracted with ether, and the ether extract tested for salicylic acid with a 0.5 per cent. solution of ferric alum. — A. S.

Lemon Oil; Determination of the Saponification Value and the Dry Residue (on the Water-Bath) of —. E. Berté. Boll. Chim. Farm., 1904, 43, 709—713. Chem. Centr., 1904, 2, 1670.

FOR the detection of adulteration of lemon oil with fat, resin, or the like, determinations of the saponification value and of the dry residue are useful. The limiting numbers: Saponification value, 3.5; dry residue, 2—3.5 per cent., are exceeded, if such substances be present in the lemon oil. In the following table the constants are given of: (a) pure lemon oil; (b) the same oil after addition of 25 per cent. of terpenes and 2 per cent. of "ordinary oil"; and (c) after addition of 50 per cent. of terpenes and 4 per cent. of "oil."

	(a)	(b)	(c)
Direct rotation at 20°C.	60.4°	61.2°	61.5°
Rotation of distillate at 20°C.	61.5°	61.5°	61.2°
Rotation of residue at 20°C.	59.1°	60.5°	61.2°
Sp. gr. at 15°C.	0.8574	0.859	0.859
Dry residue	2.46%	5.59%	7.26%
Citral (or aldehydes)	7.10%	5.70%	3.8%

—A. S.

ORGANIC—QUANTITATIVE.

Sulphur in Gas; Determination of —. W. B. Calkins. Ann. Meeting Amer. Gaslight Assoc., 1904. J. Gas Lighting, 1905, 89, 37—38.

THE method is based on the fact that when sulphur compounds such as carbon bisulphide and mercaptan are mixed with free hydrogen and passed over heated platinised asbestos or pumice, sulphuretted hydrogen is formed. A combustion tube of Jena glass, about 30 inches long, is filled loosely with platinised asbestos and placed in a combustion furnace; at one end it is connected to the meter, through which the sample of gas is to be drawn, and at the other to a train comprising two gas-washing bottles and a filter-pump. Each washing bottle consists of a glass cylinder about 9 inches high, of about 150 c.c. capacity, and contains 3 c.c. of a stock solution of cadmium chloride (prepared by dissolving "4 grains" of cadmium chloride in 100 c.c. of water and adding 100 c.c. of ammonia) mixed with 10 c.c. of strong ammonia and enough distilled water to bring the depth to about 7 inches. Before starting a test, the meter and combustion tube are filled

with the gas, the gas is shut off, and the tube heated to dull redness. The meter is now read, the gas is turned on, and drawn through the apparatus by means of the pump at a rate not exceeding 0.5 cb. ft. per hour, to avoid bubbling over of the washing liquid. A precipitate of cadmium sulphide, proportional to the sulphuretted hydrogen formed, is produced in the washing liquid. When the required volume of gas has been passed, the analysis is completed either by diluting the contents of the cylinders with a large volume of cold water, adding a large excess of concentrated hydrochloric acid to re-liberate the sulphuretted hydrogen, and titrating rapidly with iodine solution and starch, or by filtering off the cadmium sulphide precipitate, placing the filter and contents in a large volume of cold water, adding hydrochloric acid, and titrating. The reaction is:— $\text{H}_2\text{S} + 2\text{I} = 2\text{HI} + \text{S}$. The results obtained agree closely with those given by the London Gas References' method.—H. B.

Hydroxylamine; Volumetric Determination of —, with Trivalent Titanium. A. Staehle, Ber., 1904, 37, 4732—4733.

THE author observed that titanium trichloride is decolorised without evolution of gas by the action of hydroxylamine hydrochloride, the latter being reduced to ammonia:— $\text{Ti}_2\text{O}_3 + \text{NH}_2\text{OH} = 2\text{TiO}_2 + \text{NH}_3$. On this reaction he has based a method for the titration of hydroxylamine. To 21 c.c. of an approximately $\text{N}/_{10}$ -hydroxylamine sulphate solution diluted with 80 c.c. of boiling water, an excess of a standard solution of titanium trichloride—prepared by reducing titanium tetrachloride or titanium sulphuric acid in sulphuric acid solution with nascent hydrogen in a current of carbon dioxide—is added, the excess being determined by back-titration with $\text{N}/_{10}$ -ferric chloride or permanganate solution. (See Knecht, this J., 1903, 762.) The method might also be applied to organic hydroxylamine compounds.—R. L.

Antipyrine; Volumetric Determination of —, P. Lemaire, Rép. Pharm., 1904, 16, 493. Pharm. J., 1905, 74, 13.

A KNOWN volume of the solution containing antipyrine is treated with a definite excess of a $\text{N}/_{20}$ solution of picric acid and the sparingly soluble picrate is filtered off, and in an aliquot portion of the filtrate, the free picric acid is determined by titration with a $\text{N}/_{10}$ solution of sodium hydroxide, using phenolphthalein as indicator. From the data obtained, the amount of antipyrine is calculated; 1 mol. of antipyrine combines with 1 mol. of picric acid. The free picric acid left after the precipitation, may be determined approximately by comparing the colour of the filtrate with that of a picric acid solution of known strength.—A. S.

West of Scotland Technical College. Longman, Green and Co., 39, Paternoster Row, London, 1905. Price 2s. 6d.

SMALL 8vo volume, containing 130 pages of subject matter, with 28 illustrations, and an alphabetical index of subjects. A series of 127 practical exercises, with full descriptive explanations. Following these are some additional exercises in the proximate analysis of solid fuels—coal, coke, &c., and in the determination of sulphur in coal or coke.

Trade Report.

I.—GENERAL.

BRITISH TRADE DURING THE YEAR 1904.

Board of Trade J., Jan. 12, 1905

The following table shows the value of certain imports from foreign countries and British possessions for the twelve months ended 31st December last, as compared with the corresponding periods of the two previous years:—

Imports from Foreign Countries and British Possessions.*

	Year ended 31st December.		
	1902.	1903.	1904.
	£	£	£
Coal, coke and patent fuel	4,101	3,987	2,689
Iron ore, scrap iron and steel	5,091,972	4,887,793	4,598,938
Other metallic ores	5,414,737	5,915,491	6,598,921
Oil-seeds, nats, oils, fats and gums	25,234,400	24,461,171	25,281,374
Hides and undressed skins	8,019,045	7,381,872	6,571,112
Materials for paper making	3,386,773	3,431,467	3,552,162
Iron and steel and manufactures thereof	7,909,925	8,662,481	8,215,555
Other metals and manufactures thereof	19,073,337	18,511,270	20,954,681
Chemicals, drugs, dyes and colours	9,026,584	8,848,292	9,301,980
Earthenware and glass ..	4,678,473	4,780,739	4,337,282
Paper	4,537,674	4,850,183	4,940,667

* The values of the imports represent the cost, insurance and freight; or when goods are consigned for sale, the net sale value of such goods.

The value of exports of home, foreign and colonial produce during the twelve months of 1904, as compared with 1903 and 1902 include the following figures:—

Exports of British Produce.*

	Year ended 31st December.		
	1902.	1903.	1904.
	£	£	£
Coal, coke and patent fuel	27,581,136	27,262,786	26,862,387
Iron ore, scrap iron and steel	336,763	453,946	499,831
Other metallic ores	68,469	134,843	139,806
Oil-seeds, nats, oils, fats and gums	3,132,893	2,976,551	2,759,157
Hides and undressed skins	375,931	1,276,836	1,431,035
Materials for paper making	379,037	409,624	428,439
Iron and steel and manufactures thereof	28,877,337	30,399,261	28,082,692
Other metals and manufactures thereof	6,269,652	6,958,305	7,000,014
Chemicals, drugs, dyes and colours	12,757,262	13,544,552	13,651,973
Earthenware and glass ..	2,997,529	3,278,482	3,117,349
Paper	1,672,704	1,795,850	1,766,050

* The values of the exports represent the "free on board" values.

New Books.

IMPERIAL DEPARTMENT OF AGRICULTURE FOR THE WEST INDIES. SUMMARY OF THE RESULTS ON THE CULTIVATION OF SEEDLING AND OTHER [SUGAR] CANES AT BARBADOES, 1904. Issued by the Commissioner of Agriculture. Price 4d. Pamphlet of 73 pages.

EISENUNG VON GRUNDWASSER. Von L. DARAPSKY. F. Leineweber's Verlag, Leipsie, 1905.

PAMPHLET of 102 pages, illustrated with three diagrams and five wood-cuts. The subject is subdivided into short chapters as follows:—I. Occurrence and Behaviour of Ferruginous waters. II. Origin of the Iron. III. Treatment of Ferruginous waters. IV. New experiments. V. Practical arrangement of the Continuous Process for removal of iron.

LABORATORY NOTES ON PRACTICAL METALLURGY. Being a Graduated Series of Exercises. Arranged by WALTER MACFARLANE, Assessor in Metallurgy, Glasgow and

CHEMICAL TRADE IN 1904.

J. C. Finney, Chamber of Commerce J. J. Jan., 1905.

The year just closed has been in a sense a disappointing one as regards activity of business in the drug and chemical trade. Although demand has not been disturbed by abnormal variations of weather as in 1903, there has been an absence of speculation in drugs and chemicals which has left a considerable mark. There have been no important fluctuations in the prices of heavy chemicals—the prices of soda and tartaric acids remaining at a fair level until the latter part of the year, when cream of tartar and tartaric acid prices were depressed as a result of heavy vintages in France and elsewhere. There have been fluctuations in the value of a few chemicals, arising to a considerable extent from the war in the Far East. The price of camphor advanced during the early months of the year to almost famine rates—influenced to some extent by the monopoly of Japanese camphor by the Government of Japan, which came into force on October 1st, 1903. The removal of Japanese competition in iodine resulted in a considerable advance in Peruvian and Scotch iodine and their derivatives. Finally, at the close of the year there has been much appreciation in value of anti-mony, and bis-muth was advanced about 20 per cent. by the syndicate controlling its output. A very considerable reduction in the price of bromides took place in the autumn as a result of competition between European and American manufacturers, but higher prices ruled at the close of the year, and for the moment the American competition appears to be less active. The breaking-up of the arrangement regarding bleaching powder, which took place during 1902, has not been without its effect on all products prepared with that substance, and at the close of the year prices for chloroform fell in Great Britain to the lowest point on record. Speculation in quinine has not been so brisk as in previous years, and but little attention has been given during the past year to speculation in cocaine. The advance in the price of alcohol due, in a measure, to the shortage of the potato crop, has resulted in an increase in price of all substances prepared from it, namely, ether, chloral hydrate, &c., and at the present time the continental prices of spirit of wine remain so high as to leave British distillers in a most advantageous position.

IMPORT AND EXPORT LISTS: ALTERATION IN —.

Chem. and Druggist, Jan. 7, 1905.

A General Order relative to alterations in the import and export lists has been issued by the Board of Customs. It includes the following, which are to take effect from January 1:—

Import List.

Present Heading.		Future Heading.	
Chemical Manufactures and Products, etc.:		Chemical Manufactures and Products, etc.:	
Borax.....	Cwt.	Boracite.....	Cwt.
		Borate of lime.....	Cwt.
		Borate of manganese..	Cwt.
		Borax.....	Cwt.

II.—FUEL, GAS, AND LIGHT.

PEAT: CANADIAN —.

Eng. and Mining J., Dec. 22, 1904.

A practical test of the commercial value of peat from the deposits at Beaverton, Ontario, was recently given in Winnipeg. The peat briquettes burned well, and, after the consumption of the volatile matter, there remained a dense mass of glowing charcoal, which held the fire and continued to throw off heat for a considerable time. The process of manufacture used at Beaverton is simple. After the surface vegetation is stripped off, the peat is dug up by machinery and separated into minute fragments, which are scattered over the ground to dry. When most of the moisture has evaporated it is collected and compressed in an ordinary brick machine. There is very little difference in character between the Beaverton peat deposits and those in the neighbourhood of Fort Frances, in the Rainy River district, and it is proposed to operate them both on the same lines. Manufactured peat from Fort Frances could be delivered at Winnipeg at a rate which would make it cheaper than coal at present prices.

RETORT-COKE, GAS, AND BY-PRODUCTS IN THE UNITED STATES IN 1903.

Board of Trade J., Jan. 12, 1905.

The following particulars are taken from a report of the United States Geological Survey. Since 1893, when the first plant of by-product coke ovens in the United States was completed at Syracuse, New York, the quantity of coke produced in such ovens has increased so rapidly that in 1903 7.4 per cent. of the total coke product of the United States was thus manufactured. The development of this industry has been largely due to the profitable disposition made of the by-products obtained in the manufacturing process.

Reports were received in 1903 from 528 companies producing gas and coke from coal with the recovery of the tar and ammonia.

The total quantity of coal carbonised in 1903 was 5,843,538 short tons (of 2,000 lbs.). The 528 companies produced 33,483,430,989 cubic feet of gas, of which 2,433,969,478 cubic feet were lost or unaccounted for and 31,049,461,511 cubic feet were sold. Of this total 73.9 per cent. was sold for illuminating purposes and 26.1 per cent. for fuel. The average price per 1,000 cubic feet for all gas sold in 1903 was 97 cents. Prices are low in those States which have coal and natural gas among their resources. Such States are Illinois, Indiana, Kentucky, Ohio, Pennsylvania, West Virginia, and also Massachusetts, where a large portion of the coal gas made is a by-product from coke making in retort ovens.

The total production of coke amounted to 3,941,282 short tons, of which 1,882,394 short tons were obtained from by-product coke ovens, and 2,058,888 short tons were the product of gas-houses.

The total quantity of coal tar produced in 1903 was 62,964,393 gallons, valued at \$2,199,969, or 3.49 cents a

gallon. The largest production of tar in both 1902 and 1903 was in Massachusetts, with New York second, Ohio third, Pennsylvania fourth, and Alabama fifth.

Only about 20 per cent. of the companies that manufacture coke and gas reported the recovery of ammonia, either in the form of ammoniacal liquor or sulphate. The total quantity of ammonia liquor produced and sold was 61,396,662 galls., which would be equivalent to 17,479,759 lb. of anhydrous ammonia, or 67,821,165 lb. of sulphate. The total quantity of sulphate of ammonia produced and sold in 1903 was 11,925,752 lb. The total production in 1903, reduced to its equivalent in sulphate, was 79,747,217 lb.

Comparatively little progress has been made in the United States in the manufacture of chemical products from coal tar. Although over 50,000,000 galls. of coal tar are produced annually, millions of dollars' worth of chemicals obtained from coal tar are imported every year.

(France), and other pyroxylin silks are stated to be produced at Spreitenbach and Zollikofen (Switzerland), Wolston (England), and Elberfeld. The Besançon factory is now producing about 3600 lb. daily. "Viscose silk" is manufactured at Lansdown, Pa., U.S.A., about 300 lbs. per day being produced. A factory near Stuttgart was, in October, 1903, producing 50 lb. per day, and had a capacity for 2000 lb. per day. Artificial silk fibre to the value of \$170,000 was imported into the United States during the year ended June 30, 1902, and in the succeeding year the value of the imports in question had risen to \$134,033.—T. F. B.

VII.—ACIDS, ALKALIS, AND SALTS.

NITRATE OF SODA STATISTICS.

W. Montgomery and Co., Dec. 31, 1904

Shipments, Consumption, Stocks, and Prices, from 1902 to 1904.

	1902.	1903.	1904.
Shipments from South American ports to all parts for the six months ending 31st December	765,000	885,000	870,000
Ditto do. for the twelve months ending 31st December	1,360,000	1,435,000	1,457,000
Afloat for Europe on 31st December	397,000	499,000	496,000
Stocks in U.K. ports:—			
	1902.	1903.	1904.
Liverpool Tons	6,500	4,500	6,000
London "	3,600	4,100	2,100
Out ports "	15,900	14,400	12,900
Stocks in Continental ports on 31st December	237,000	132,000	141,000
Consumption in U.K. for the 6 months ending 31st December	35,000	33,000	43,000
Do. in Continent do.	249,000	263,000	261,000
Do. in U.K. for the 12 months do.	111,000	110,000	121,000
Do. in Continent do.	917,000	1,017,000	1,010,000
Do. in United States do.	214,000	265,000	275,000
Do. in other Countries do.	17,000	20,000	41,000
Do. in the World do.	1,259,000	1,412,000	1,447,000
Visible supply on 31st December (including the quantity afloat for Europe and stocks in U.K. and Continent)	660,000	654,000	658,000
Price on 31st December	9/1½	9/7½	10/10½

A conservative estimate would place the total value of these products in the wholesale markets of the United States of America at \$12,000,000.

Note.—United States gallon = .833 Imperial gallon.

III.—TAR PRODUCTS, PETROLEUM, Etc.

TAR DISTILLATION.

Home Office, Jan., 1905.

In October, 1903, a memorandum was issued by the Department calling attention to the risks incurred by persons employed in works in which is carried on the distillation of tar and the production of naphtha, light oil, creosote oil, and pitch (see this J., 1903, 1265). The precautions suggested therein have been generally adopted, but it has been found necessary to modify paragraph 5 (see p. 1266) to read as follows:—

"The inspecting foreman on first entering any tar still or tank, and all persons employed in tar stills or tanks in which there are no cross stays or obstructions likely to cause entanglement, should be provided with a belt securely fastened round the body, with a rope attached, the free end being left with two men outside whose whole duty should be to watch and draw out any person appearing to be affected by gas. The belt and rope should be adjusted and worn in such a manner that the wearer can be drawn up head foremost and through the man-hole, and not across it."

V.—TEXTILES, YARNS, AND FIBRES.

SILK: ARTIFICIAL.—

Bull. of the Imperial Institute (Supplement to the Board of Trade J.), 1905, 2, 269.

The de Chardonnet process is worked at Besançon

AMMONIUM SULPHATE STATISTICS.

Bradbury and Hirsch, Jan., 1905.

The total production of ammonia, calculated as sulphate (including that used in the ammonia-soda and other chemical processes) from all sources in the United Kingdom during 1904, is estimated as below, figures for the preceding three years being given for comparison:

	1901.	1902.	1903.	1904.
	Tons.	Tons.	Tons.	Tons.
Gasworks	143,000	150,000	150,000	154,000
Iron	16,500	18,500	19,000	19,000
Shale	40,000	37,000	37,500	39,500
Coke and carbonising works and producer gas	18,000	23,500	27,500	32,000
	217,500	229,000	234,000	244,500

Of the 1904 production, England contributed 162,400 tons, Scotland 79,500 tons, and Ireland 2,600 tons.

The exports during 1904 amounted to 177,000 tons, and home consumption 68,500 tons, leaving stocks on hand on Jan. 1 of about 11,000 tons. Average prices for good grey 24 per cent. sulphate, f.o.b. Hull, fell from £12 14s. 3d. per ton in January to a minimum of £11 13s. 1½d. in August, but rose again from October, reaching £12 14s. 9d. in December.

POTASH SYNDICATE: GERMAN.—

Chem. and Druggist, Jan. 7, 1905.

The general director of the German Potash Syndicate states that the total turnover of the combination in clear

potash will probably amount to 416,500 tons for 1904, or an increase of 54,900 tons over the previous year. After deducting expenses, it is estimated that the year will close with total receipts amounting to over £3,650,000 or £450,000 in excess of the income earned in 1903. It is hoped to counteract to some extent the competition of out-standing potash-works and any possible reduction in prices next year by further increasing the sales of the syndicate.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

EMERY TRADE AND INDUSTRY OF NAXOS.

Foreign Office Annual Series, No. 3179.

Emery is found almost exclusively in Greek territory. Of a total production of about 30,000 tons, 20,000 come from the vilayet of Smyrna, 5,500 from the island of Naxos, and 4,500 from the United States, where the working of emery mines dates only from 1871. Apart from American emery, of which the prime cost is still too high to enable it to compete, it is stated that the emery of Naxos, is both superior in quality, and less costly than the similar product of Asia Minor, where the cost of mining, to which must be added the cost of transport to Smyrna, is greater than in the Archipelago. The Greek Government has reserved the monopoly of it since 1824. The right of raising the mineral is reserved to the native peasants of the mining districts who have to transport the emery to one of the bays for loading. There the fiscal authorities take delivery at a fixed price of 43 dr. 20 c. per ton, and transport it to the depôts at Syra, whence it is exported to foreign countries. The cost of transport from Naxos to Syra brings the cost of production up to about 52 dr.; the fiscal authorities, on their part, sell at the fixed price of 106 fr. 50 c. per ton, the difference between these two figures representing the value of the monopoly, which is one of the revenues assigned to the service of the public debt. In recent years the exploitation of emery has been the object of several reforms. More care has been given to selecting the product mined, which has led to an improvement in the quality; the State has constructed depôts at Syra, which have facilitated the development of the exportation by rendering loading easier, and by assuring more regularity in the trade. Hence the exports of emery which amounted in 1897 to 3,125 tons, value £13,515, reached in 1903, 5,813 tons, value £24,763. But in spite of the progress which has been achieved, the emery does not afford to the Government such returns as might reasonably be expected. Beyond the fact that more perfect processes might be employed in its extraction by the Naxiotes, cargoes composed of three parts of Smyrna emery are often completed at the depôts at Syra, and then sold to consumers as solely Naxos produce. The danger of American competition consists not merely in an increase of production in the United States, and consequently a lowering of the price of natural emery, but also in the invention of certain artificial substitutes such as carborundum and "steel emery." Such competition would be very serious as more than half the world's production (16,500 tons out of a total of about 30,000 tons) is consumed annually in America.

X.—METALLURGY.

MERCURY IN 1904; BRITISH TRADE IN —

A. S. Pickering, Jan., 1905.

It will be observed from the table below that while

	Imports. Bottles.	Exports. Bottles.	Price.			
			Highest.	Lowest.		
			£ s. d.	£ s. d.	£ s. d.	£ s. d.
1904	33,218	27,277	8 5 0	7 14 0		
1903	34,886	18,846	8 15 0	8 5 0		
1902	33,192	19,519	8 17 6	8 14 6		
1901	35,341	26,863	9 2 6	8 17 6		
1900	32,725	25,869	9 12 6	9 2 6		
1895	49,654	36,827	7 8 6	6 7 6		

the exports during 1904 were 27,277 bottles, which are larger than the last four years, the imports remain about normal; while the present price of £7 15s. being the lowest officially for six years, rather points to higher rates presently prevailing. The demand for home consumption keeps up to the average, with the result that stocks are diminishing.

IRON ORE TRADE; BELGIAN —.

Eng. and Mining J., Dec. 29, 1904.

In the ten months ending October 31, imports of iron ore into Belgium were 2,823,266 tons, an increase of 240,341 tons over last year. The exports of iron ore—chiefly to Luxemburg—were 345,080 tons in 1903, and 380,775 tons in 1904, showing an increase of 35,695 tons.

XIII. FATS, FATTY OILS, Etc.

OILS; EXPORTS OF —, FROM MARSEILLES TO THE UNITED STATES.

U.S. Cons. Rep. No. 2141, Dec. 24, 1904.

Exports of Marseille oils to the United States were heavier in 1904 than usual, the declared value of such exports during the fiscal year ended June 30, 1904, having been as follows:—

Oils.	Value.
	Dols.
Almond	150.54
Castor	3,322.01
Copra	14,574.20
Cotton-seed	625.80
Essential	2,264.65
Olive, edible	243,882.23
Olive, for manufacturing	112,464.86
Poppy	153.43
Peanut, edible	974.26
Peanut, manufacturing	55,910.65
Sesame	41,276.71
Various including medicinal	1,710.17
Total	477,309.51

XIV.—TANNING; LEATHER; GLUE, Etc.

TANNING MATERIALS; PRODUCTION OF —.

Bull. of the Imperial Institute (Supplement to the Board of Trade J.) 1905, 2, 274—276.

The following particulars are taken from a leaflet issued by the Biological Agricultural Institute at Anani (German East Africa) relative to certain tanning materials considered suitable for the colony:—*Rhus Species*. One of the most important is *Rhus coriaria* (from which sumach is obtained) which is grown in Sicily, Spain, Portugal, Greece and Cyprus. The plant grows well on sunny slopes of dry, sandy and barren soil; when grown on rich soil, the plant is deficient in tannin. The leaves are dried in the sun, powdered and exported. After about 15 years' growth the shrubs cease to yield leaves rich in tannin. The tannin content of sumach leaves varies from 23 to 27 per cent., occasionally reaching 30 per cent. *Rhus semilata* is indigenous to Japan and China, but grows freely in the Himalayas and in Assam. Its galls contain from 60.70 per cent. of tannin, and are an important source of gallotannic acid. *Rhus vernicifera* and *Rhus succedanea* are indigenous to Japan, and are widely distributed in other sub-tropical and temperate countries. The former yields the valued "Japan lacquer" whilst the latter is cultivated mainly for the sake of its wax (Japan wax). The leaves of both varieties contain small quantities of tannin similar to that obtained from sumach. *Rhus hypocosepalus* yields the material known as "canaigre" or "tanners' dock," and is indigenous to the United States and to Cuba. It has been successfully introduced into Madagascar. The plants require a light, sandy, alluvial soil, with heavy rainfall. The roots of the plant are sliced into thin pieces, dried at

60° C., and extracted with water at 56° C., to produce a canaigre extract; the solution is evaporated *in vacuo* and the residue dried; it contains about 75 per cent. of tannin. The dried roots contain on the average 26 to 38 per cent. of tannin. The yield of dried root is from 10 to 20 tons per acre. *Casalpinia coriaria*: The pods of this tree, which is indigenous to Central America, and is now cultivated in Java, India and Australia constitute the material divi-divi. The tree, which yields a profitable crop until it is about 25 years of age, requires a fairly dry, light soil, and does best at an altitude of 1,500-2,500 feet. The ripe pods are broken up and the husks are dried in the sun, the seeds being rejected. American divi-divi and pods are said to yield 30-50 per cent. of tannin; those from India usually contain about 30 per cent. (See this J., 1904, 794.)—T. F. B.

XVII.—BREWING, WINES, SPIRITS. Etc.

ALCOHOL LAW; NEW PERUVIAN —.

Board of Trade J., Jan. 5, 1905.

A Peruvian decree provides for the freeing of denatured alcohol from fiscal duties and municipal taxes in that country from Oct. 27, 1904. The denaturation is to be effected by adding to every 100 litres of alcohol 10 litres of methylene and one gram of Malachite Green or a decigram of Fluorescein. The methylene (according to the decree) should show 90 alcoholometric degrees, and contain a maximum of 40 degrees of methyl alcohol. Those engaged in denaturing alcohol must be registered, and the denaturing has to be performed in special receptacles, and on the estates where alcohol is produced or at the distilleries. In both cases it has to be done in an independent department and in the presence of two employees of the Tax Collecting Co.—apparently a body to which the collection of taxes is "farmed" by the Government. This organisation supplies the denaturing and colouring matters named, for which the registered person using them has to pay cost. He, however, is not called upon to meet the expenses of the officials. He cannot sell quantities of less than 50 litres, and only tradesmen can retail. Not less than a hectolitre can be denatured, and the denaturing of alcohol which contains less than 78 per cent. of absolute alcohol is strictly prohibited under penalty. Also the re-naturing of alcohol is prohibited, and the infraction of this is punishable by forfeiture and fines, the infringer also being liable to an action as a defrauder of the State.

"CENTRALE FÜR SPIRITUSVERWERTHUNG," 1903-4; REPORT OF THE TECHNICAL SECTION OF THE —.

Z. Spiritusind., 1904, 27, 523.

In spite of the increased price of alcohol, the consumption of denatured spirits in Germany in the year 1903-4 increased to 11 million litres. The sale of spirit-consuming apparatus also showed a marked increase, that of lamps having almost doubled in the last year. The use of alcohol for lighting purposes has made enormous progress. Satisfactory incandescent burners for spirits are now on the market. They consume 20—25 c.c. of spirits per 10 candles per hour, and have to some extent even displaced gas and electricity. The use of spirits for cooking and laundry purposes has shown no perceptible increase. As regards motors, the consumption of alcohol has increased from 2.4 million litres in 1902-3 to 3.6 million in 1903-4; the number of alcohol motors in Germany is about 2000. This increase is mainly due to the fact that spirits for motor purposes were exempt from the general rise in price of 5 pf. per litre. In the year 1904-5, however, an increase of 10 pf. per litre has been imposed on motor spirit, which may restrict further progress. In view of this, the practice of carburetting the alcohol by admixture with benzene may be extended.—J. F. B.

Patent List.

N.B.—In these lists, A. means "Applicant on" and C.S. "Complete Specification Accepted."

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are, in the case of Applications for Patents, the dates of application, and not in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

 „ 29,057. Meirowsky. Electric insulation. Dec. 30.
 „ 29,065. Butler. Dry batteries. Dec. 30.
 „ 29,129. Blackmore. Electromagnetic separators. Dec. 30.

- [A.] 29,138. Day (Empire State Dry Battery Co.). Dry batteries. Dec. 30.

1905.

- „ 250. Lorenz and Crane. Solution for the formation of accumulator plates. Jan. 5.
 „ 315. Thompson (Pflüger Accumulatoren-Werke). Plates for secondary batteries. Jan. 6.
 [C.S.] 2152 (1904). Raschen, Clayton, and United Alkali Co., Ltd. Electrolytic cells. Dec. 31.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

1904.

- [A.] 28,442. Arledter. Utilisation of waste products in the manufacture of soaps or soap size. Dec. 27.
 „ 28,671. Buchanan. Filters for linseed and other oils. Dec. 29.
 „ 28,939. Hutcheson. *See under XIII. B.*
 „ 28,987. Goulton. *See under V.*
 „ 29,081. Holmblad. Candles. Dec. 30.
 „ 29,463. Lorrain. Method of manufacturing candles. Dec. 31.
 „ 29,494. De Witt. Candles. Dec. 31.
 „ 29,542. Strange. Process of refining linseed oil. Dec. 31.
 „ 29,558. Bradford, Garfield and Grossmann. *See under XVIII. B.*

1905.

- „ 46. Soc. Anon. "Union." *See under XVIII. A.*
 „ 207. Day and Murch. Candle making machines. Jan. 4.
 [C.S.] 4415 (1904). Castle. Manufacture of soap, washing compounds, and the like. Dec. 31.
 „ 6080 (1904). Slater and Slater. Manufacture and subsequent treatment of soap. Dec. 31.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, ETC.

(A).—PIGMENTS, PAINTS.

1904.

- [A.] 29,141. Davey. Manufacture of vegetable black.* Dec. 30.
 „ 29,245. Ojeda and Quesada. Copying inks.* Dec. 31.
 „ 29,335. Moreton and Tregarthen. Paint compositions. Dec. 31.
 [C.S.] 4447 (1904). Smith and Beswick. Writing fluid. Dec. 31.
 „ 6839 (1904). Johnson (Badische Anilin und Soda Fabrik). *See under IV.*

(B).—RESINS, VARNISHES.

1904.

- [A.] 28,939. Hutcheson. Method of clearing and brightening varnishes and vegetable and animal oils. Dec. 30.
 „ 29,379. Marks (Holtkott). Machines for manufacturing linoleum. Dec. 31.

(C).—INDIA-RUBBER.

1901.

- [A.] 28,574. Frost. Vulcanising apparatus. Dec. 28.
 „ 29,311. Frost. Vulcanising apparatus. Dec. 31.

1905.

- „ 330. Thomson (Michie and Gollidge). Method of separating or coagulating india-rubber and appliances therefor. Jan. 7.

XIV.—TANNING; LEATHER, GLUE, SIZE, Etc.

1904.

- [A.] 29,003. Staynes. Manufacture of leather. Dec. 30.
 „ 29,130. Adam (Erste Triester Reisschäl Fabrike Act.-Ges.). Manufacture of sizing or finishing media. Dec. 30.

1905.

- „ 363. Lake (Schoellkopf, Hartford and Hanna Co.). Depilatory Composition.* Jan. 7.

XVI.—SUGAR, STARCH, GUM, Etc.

1904.

- [A.] 28,987. Goulton. *See under V.*
 [C.S.] 5574 (1904). Kantorowicz. Manufacture of new products from starch, dextrin or the like. Dec. 31.

XVII.—BREWING, WINES, SPIRITS, Etc.

1904.

- [A.] 28,619. Schrottky. Manufacture of beer.* Dec. 28.
 „ 28,809. Rosalt. Treatment of alcohols. Dec. 29.
 „ 28,951. Lennox. Evaporators for evaporating the liquid in brewers' wash, sewage, waste or spent dyes, and the like. Dec. 30.
 [C.S.] 4651 (1904). Allitt. Apparatus for treating brewers' wort for cooling and other purposes. Dec. 31.

XVIII.—FOODS; SANITATION, WATER PURIFICATION; & DISINFECTANTS.

(A).—FOODS.

1904.

- [A.] 28,374. Dubuisson. Process and apparatus for the preservation of natural butter. Dec. 27.
 „ 28,415. Kunick and Elworthy. Methods of homogenising milk and apparatus therefor. Dec. 27.
 „ 29,367. Mills (Bévenot and De Neveu). Desiccation and preservation of milk, cream, casein and their derivatives. Dec. 31.
 „ 29,427. Howorth (Whetham). Apparatus for treating flour for improving the colour thereof. Dec. 31.
 „ 29,543. Hemming. Method of and apparatus for sterilising and aerating foods, liquids and organic substances and treating other materials with gases. Dec. 31.

1905.

- „ 28. Hatmaker. Eggs and egg-containing substances in dry form and process for obtaining same. Jan. 2.
 „ 46. Soc. Anon. "Union." Process of improving and refining margarine and the like.* Jan. 2.

- [C.S.] 16,351 (1904). Soc. Anon. des Rizerie Française. Treatment of rice flour with a view to its substitution for various starches used in sizing and finishing. Jan. 11.

(B).—SANITATION; WATER PURIFICATION.

1901.

- [A.] 28,403. Lines. Deodorisation of sewage and other gases, and the treatment of sewage and other liquids. Dec. 27.
 „ 28,646. Spence, and Spence and Sons, Ltd. Treatment and utilisation of sewage. Dec. 29.
 „ 28,951. Lennox. *See under XVII.*
 „ 29,315. Candy. Sterilisation and purification of water. Dec. 31.
 „ 29,558. Bradford, Garfield and Grossmann. Method and apparatus for recovering fatty and oily matter from sewage sludge. Dec. 31.

1905.

- „ 276. Adams. Apparatus for sewage purification. Jan. 6.
 [C.S.] 16,934 (1904). Lake (Jewell). The purification of water. Dec. 31.

XIX.—PAPER, PASTEBOARD, &c.

1904.

- [A.] 28,454. Bloxam (Verein. Glanzstoff-Fabr. Act.-Ges.). *See under V.*
 „ 28,712. Tompkins and Crombie. *See under V.*

1905.

- „ 248. Matas y Rodes. Manufacture of cork compositions.* Jan. 5.
 [C.S.] 4907 (1904). Pope and Hübner. *See under V.*
 „ 4996 (1904). Jackson. Manufacture of paper pulp from printed paper. Dec. 31.
 „ 5286 (1904). Howorth (Soc. Franç. de la Viscose). Apparatus for treating viscose. Jan. 11.
 „ 5730 (1904). Howorth (Soc. Franç. de la Viscose). Apparatus for the treatment of viscose. Jan. 11.
 „ 23,245 (1904). Loria. Method of and apparatus for the continuous manufacture of cardboard. Jan. 11.
 „ 25,726 (1904). Tailfer. Paper-making machines. Dec. 31.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

1904.

- [A.] 29,330. Howorth (Morana Co., Akt.-Ges.). Process for the production of sulphuretted hydrocarbons. Dec. 31.

1905.

- „ 81. Imray (Soc. Chem. Ind. in Basle). Manufacture of *c-c*-dialkylbarbituric acids. Jan. 2.
 [C.S.] 16,602 (1904). Kalle und Co. Manufacture of bromine alkylacetamides. Dec. 31.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

1904.

- [A.] 28,544. Cleave. Process of producing and fixing photographic portraits in natural colours. Dec. 28.

- [C.S.] 4941 (1904). Heseckel. Colour photography. Dec. 31.
- .. 4994 (1904). Imray (Meister, Lucius und Brüning). Manufacture of coloured photographic images or prints and of sensitive surfaces therefor. Dec. 31.
- .. 25,718 (1904). Soc. Anon. des Plaques et Papiers A. Lumière et ses fils. Sensitised plates for a process of colour photography. Jan. 11.
- .. 26,247 (1904). Morgan. Manufacture of sensitive photographic printing papers of the class known as self-toning printing out papers. Jan. 11.

XXII.—EXPLOSIVES, MATCHES, Etc.

1904.

- [A.] 28,808. Central-stelle f. Wissenschaftlich-Techn. Untersuch., G.m.b.H. Manufacture and use of dinitroglycerine. [Ger. Appl., March 18, 1904.]* Dec. 29.

- [A.] 29,056. Dittmarr. Explosive or blasting compounds.* Dec. 30.
- .. 29,459. Brodie, and the British Moss Litter Co., Ltd. Manufacture of explosives. Dec. 31.

1905.

- .. 159. Thorn. Matches.* Jan. 3.
- [C.S.] 25,797 (1904). Johnson (Soc. Anon. des Poudres et Dynamites). Manufacture of explosives. Dec. 31.

XXIII.—GENERAL ANALYTICAL CHEMISTRY.

1904.

- [A.] 28,585. Gonnermann. Device for determining the percentage of salt in sea water or other water contained in closed receptacles. Dec. 28.

JOURNAL OF THE Society of Chemical Industry.

A RECORD

FOR ALL INTERESTED IN CHEMICAL AND ALLIED MANUFACTURES.

ISSUED TWICE A MONTH.

No. 3.—Vol. XXIV.

FEBRUARY 15, 1905.

No. 3.—Vol. XXIV.

Subscription of Members 25 - per annum;
Entrance Fee 21 -;
Election by the Council.

Price to Non-Members 36 - per annum.
To Members 25 - per Set of extra or back numbers.
Single copies (Members and Subscribers only)
1882—1901, 2 6 each, 1902 *et seq.*, 1 9 each.

The Society of Chemical Industry.

Past Presidents:

Sir Henry E. Roscoe, B.A., D.C.L., LL.D., Ph.D., F.R.S.	1881—1882.
†Sir Frederick A. Abel, Bart., K.C.B., G.C.V.O., D.C.L., D.Sc., F.R.S.	1882—1883.
†Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, LL.D., Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Sir James Dewar, M.A., LL.D., F.R.S.	1887—1888.
Ludwig Mond, Ph.D., F.R.S.	1888—1889.
†Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
†E. Rider Cook	1890—1891.
J. Emerson Reynolds, M.D., F.R.S.	1891—1892.

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps in the verification of addresses, on which the safe delivery of the Journal depends.

Meeting held in the Chemical Department, University of Toronto, on Feb. 26th, 1903.

DR. HAROLD VAN DER LINDE IN THE CHAIR.

THE RECOVERY OF TIN SCRAP.

BY JAMES MILLAR NEIL.

The annual average quantity of scrap tin, collected from can factories, &c., in the United States, is from 0,000 to 30,000 tons, and of that amount about 24,000 tons are treated there for the recovery of the tin and iron, the rest being sent to Germany for treatment. The principal recovery works are situated at Chicago, Cleveland and Jersey City.

A few years ago scrap tin was thrown away, but to-day it is pressed into bundles weighing about 250 lb. each, and shipped to the recovery works, and fetches 13.50 dols. per long ton in New York.

Tin plate was formerly made from puddled iron of the very best quality, and contained on an average about 1 per cent. of tin; to-day it is made from sheets of mild steel dipped into a bath of molten tin and passed through rollers, whereby an enormous pressure is applied, until only the very thinnest possible coating of metallic tin remains, rarely reaching 2 per cent.

There is one source of scrap tin which would increase the quantity if it could only be utilised, and it is that of old cans, as nearly all the tin plate is used to make cans for reserved goods. But in practice these old cans are hardly worth special collection, and must usually be retrieved from dust bins and rubbish heaps, and the supply is apt to be uncertain. Next, they have to be completely cleaned before treatment; they are bulky and troublesome to handle; they are inconvenient to strip either electrolytically or by chemical reagents; so that until these difficulties are overcome, the recovery works have to depend upon the cuttings from the new tin plate, which is clean and capable of being packed at a small expense, into a size easy to handle.

The tin recovered has a value of about 25 cents per lb., and the residue of stripped iron has a value depending entirely on its freedom from tin.

Scrap tin packs so closely together that difficulty is experienced in getting every particle of tin into contact with the solvent. The stripped iron, due to its bulky nature, is not a favourite with iron workers, and it can only be used to advantage in an open hearth furnace, and then perfectly free from tin is worth at the present time about 14.00 dols. per ton, f. o. c. at the iron works. Traces of tin render the finished iron brittle and liable to crack during welding.

Prof. Richards, of the Franklin Institute, Philadelphia, devised a process for the separation of tin and iron in tin scrap, which is fully described in the Society's Journal, 901, 902.

The processes that are having a practical success may be classed under the following heads:—

Purely electrolytic processes, the caustic soda electrolytic process, the stannic chloride process, the Browne-Neil electrolytic process.

Under the purely electrolytic processes, that of P. Nauhardt, Germany, has very good prospects of giving satisfactory results. (Eng. Pat. 21,942 of 1901; this J., 902, 261 and 864.) This process would be an ideal one if it were not that there has yet to be found a rotating drum which will expose, for a sufficient length of time, every part or side of the scrap-tin under treatment, so that the electric current will have time to strip off the tin. Again, it is very costly to fill and empty such drums having scrap tin under treatment; besides, in order to make them strong enough to hold the scrap, they would have such a very small electrolytic surface exposed that the outlay in plant would be excessive.

In all purely electrolytic processes the difficulties lie

in that the current can only strip off the tin on the surface which comes under its action, and in the finding of some practical scheme whereby the surface of the scrap may be changed about so that every part of tin may be stripped.

One of the most important processes, is the stannic chloride one invented by P. Bergsøe, of Copenhagen, and which is now worked in Germany. (Eng. Pat. 7026 of 1900; this J., 1901, 368.)

The principal drawback to his process is that while the scrap tin is being treated with stannic chloride, the latter not only attacks the tin, but also dissolves a good part of the iron, thereby causing a heavy loss of chlorine, and every time it is used the efficiency of the stannic chloride solutions becomes reduced by the amount of iron dissolved. Another drawback is the facility with which these stannic compounds form oxides, which cause precipitates in the electrolytic bath.

Caustic soda, while an electric current is being passed through it, dissolves tin from scrap tin, without touching the iron, and this property is utilised in recovery works to-day; but even with the very best skill in working this process there remains a small percentage of metallic tin on the cleaned scrap—about 0.2 per cent. Full details of this process are given by H. Mennecke (this J., 1902, 980).

The Browne-Neil electrolytic process (this J., 1902, 1083) utilises the reduction of ferric chloride by tin, with the result of obtaining very pure tin and an iron absolutely free from tin.

The scrap tin bundles are first cut open and tossed about, so as to open up the scrap. This is then thrown into large reed baskets, holding about 200 lb., which are then lowered into concrete vats containing a concentrated solution of ferric chloride, kept at boiling point. This solution attacks the tin at once, completely forming stannous chloride and ferrous chloride. The moment that all the tin is off, the basket of cleaned scrap iron is drawn out, and another basket with fresh scrap tin is lowered in, and so on until the whole of the ferric chloride solution becomes reduced. The cleaned iron is then washed, after which it is dipped into a tank of petroleum to keep it from rusting, and then bundled ready to be shipped to the iron works.

The ferrous stannous chloride solution is now run into a series of electrolytic baths, the outside one being made of concrete, and the inside or inner ones being made of porous clay. In the outer ones a small stream of the ferrous stannous chloride solution is kept running continuously, and into the porous cells is run a solution of ferrous chloride, derived from the last of the series of the concrete baths. The cathode consists of sheets of pure tin, and the anode of graphitised carbon. The whole series of baths are then connected on to the electric current. In its flow the ferrous stannous chloride solution as deposit on the cathode large bright crystals of pure metallic tin, while the chlorine liberated at the anode immediately converts the ferrous chloride solution flowing through the porous baths, into ferric chloride, which is pumped back to the dipping tank to be again reduced by fresh scrap tin. So that in the first of the series of plating baths a continuous stream of ferrous stannous chloride solution passes through the outer chamber, which deposits its tin and becomes gradually richer in ferrous chloride until, as it leaves the last of the series, it contains no tin at all. It is this solution of ferrous chloride which is run through the porous baths, and by absorbing the chlorine becomes converted into ferric chloride.

After a day's run, the tin crystals are taken from the baths and thrown on to a filter, where they are allowed to drain, then washed with slightly acidulated water, dried, pressed into plugs and then melted.

The process thus described appears to be continuous and simple, but when worked out on a practical scale presents difficulties. In the first place, in order to secure iron that is absolutely free from tin, some of the iron—about one-half of the amount of tin on the scrap tin—must be allowed to be dissolved by the ferric chloride, chlorine corresponding to which must be put back into the process by the plating out of the amount of iron dissolved. Again, it is impossible to get all the tin dissolved

off the scrap iron by the lowering of the basket into the tank of ferric chloride, and to get the result desired it was necessary to draw the basket an upward and downward movement. In this way was obtained a scrap iron free from metallic tin.

The plating baths are in series of five large concrete tanks, each containing ten porous boats; in the first three boats a gradually pure tin is obtained, in the fourth the tin is mixed with about 20 per cent. metallic iron, whilst in the last of the series, the flow of ferrous solution of ferric solution is regulated so that enough tin will be present to give the chlorine necessary to make an insoluble ferric chloride solution coming from the last of the baths. In the plating baths, the tin comes in the form of 20, sparkling crystals in the first two baths, and gradually gets darker in each succeeding bath. The amount of tin carried is about 25 grs. per lb. as it comes from the dipping tanks.

The iron and tin crystals obtained in the fourth tank are used to reduce any stannic or ferric chloride that may remain in the liquor coming from the dipping vats, and as the test for running off the dipping vats is simply that of the change of colour from the red of the ferric to the green of the ferrous, this precaution is absolutely necessary in order to obtain pure crystals of tin, and to have full efficiency from the electric current.

Again, one is free to use either concrete or porcelain in all the apparatus required, as wooden tanks rot away in a very short time, and metals of any kind are out of the question; besides all pumps, &c., have to be of earthenware.

The sample of pig iron made from the clean iron scrap is exceedingly hard, owing to the deficiency of carbon, and hardens half way between cast iron and cast steel.

There is obtained 34 lb. of pure metallic tin every 24 hours, at an electrical expense of 2-3 h.p. per hour. The strength of the electric current carried on each series of baths is 25 volts at 500 amperes and the sizes of baths are so calculated as to carry on each $\frac{1}{2}$ sq. in. a current of 200 amperes.

The amount of tin recovered per ton of scrap treated is 40 lb.

Obituary.

SIR JOHN NEILSON CUTHBERTSON,

FORMERLY CHAIRMAN OF THE GLASGOW AND SCOTTISH SECTION OF THE SOCIETY OF CHEMICAL INDUSTRY.

John Neilson Cuthbertson was born in 1829, and educated at the High School and University of Glasgow; also at the Royal College, Versailles. In the Chemical Trade he held a high position as a chemical and produce broker. He was a member of the University Court, Glasgow, and a Governor of the Glasgow and West of Scotland Technical College.

In 1887, Sir John Cuthbertson was elected the Chairman of the Glasgow and Scottish section of this Society, and in the same year he received the honour of knighthood; also the degree of LL.D. was conferred upon him by the University of Glasgow, in 1895. For twenty-five years he was a member of the Glasgow School Board, and for fifteen of these, he occupied the position of chairman. He was one of the best known public men in Glasgow and the West of Scotland, and especially distinguished himself in works of philanthropy and benevolence.

He died January 26th, at the age of seventy-five.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—3d. each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—1s. each, to the Secretary of the Society.

French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs-Bourgeois, Paris (3^e).

I.—PLANT, APPARATUS, MACHINERY.

ENGLISH PATENTS.

Centrifugal Apparatus for Evaporating, Cooling, Heating, Absorption, Gas-Purifying, and like purposes. E. Theisen, Munich, Germany. Eng. Pat. 25,478, Nov. 21, 1903.

A centrifugal apparatus, in which a gas and a liquid are made to rotate together by means of a "winged" drum working in a casing, the fluid is guided on the surface of the casing by flanges or channels of suitable inclination in spiral form, arranged on the inner surface of the casing, in this manner a forward movement is given to the liquid in motion by the current of gas. The speed of the liquid can be regulated by altering the inclination of the guiding flanges or channels.—W. H. C.

Dissolving, Filtering, Condensing, Evaporating, and Separating Substances; Apparatus for —. C. H. Rider, St. Louis. Eng. Pat., 9635, April 27, 1904.

CLAIM is made for the combination of an acid-tank and a water-tank, connected by suitable pipes and valves to an upper series of tanks and also to a lower series of tanks. The upper series of tanks is connected with the lower series and each tank with the other. A retort (e.g., for making nitric acid) set in a furnace has a pipe leading through the lower series of tanks to a condenser. The upper series of tanks is connected with the pipe from the retort and the latter is also connected with a gas-holder. Any desired mixture of acid and water may be made in the upper series of tanks and allowed to flow on to the material (e.g., ores, &c.) to be treated, contained in the lower series of tanks, which are provided with false bottoms. The contents of the lower series of tanks are heated by the vapours passing from the retort, any uncondensed gas being collected in the gas-holder.—W. H. C.

Concentrating Liquids, Apparatus for —, especially adapted for Removing the Aluminous Matter from Serum and the like Liquids. H. W. Southworth, London. Eng. Pat. 24,870, Nov. 16, 1904.

A SCREW conveyor, mounted in a hollow shaft, is arranged to work in an inclined jacketed tube or shoot, the inclination of which can be varied as desired. The material to be treated is fed in at the upper end, and is cooled by the circulation of a cooling agent through the jacket and hollow shaft. The screw-conveyor carries the deposited solids separated from the liquid by the cooling, to the upper end of the shoot, where they are discharged, whilst the liquid works its way downwards, through slots and perforations in the blades of the conveyor, to the outlet at the lower end. The feed-pipe is provided with a valved overflow-pipe leading to a tank, into which, if the apparatus clog, the liquid overflows and operates an electric alarm signal. There is also a "gate" which is opened automatically if pressure accumulate in the shoot, and has an electric alarm signal. In order to prevent the clogging of the blades of the conveyor, a portion of the upper surface of the tube is cut away, and in the rectangular slot so formed, a series of V-shaped "wipers," of glycerined raw hide, carried on an endless band, clears the spaces between the blades of the screw-conveyor.

—W. H. C.

Kiers; Vomiting —. A. J. Boulton, London. From E. D. Jefferson, Lowell, U.S.A. Eng. Pat. 25,397, Nov. 21, 1904.

SEE U.S. Pat. 775,450 of 1904; this J., 1904, 1022.—T.F.B.

Earthenware Cocks for Use with Acids, Lyes and the like; Impts. in Protected —. C. Ruppel, Höchst-on-the-Maine, Germany. Eng. Pat. 25,310, Nov. 21, 1904.

A PROTECTED earthenware cock is made with its body entirely cylindrical and limited in length to just beyond what is necessary for the plug. The earthenware body is surrounded by a metal protective casing, provided with lateral "reinforcements," through which the holes for the bolts, which connect the cock with the piping, pass. Ribs

are formed on the outer side of the casing, and the liquid that may escape around the plug, flows on to the flange joints. In another form of casing, on the metal casing is a cylindrical, water-tight cap, fixed upon the ends, to receive screwed caps, to be used with the piping. When the protective casing is of soft metal, an outer casing of hard metal, provided with threaded ends may be used.—W. H. C.

UNITED STATES PATENTS.

Separator; Centrifugal Liquid —. J. H. F. Dorn, and C. J. Möllmann, Osnabrück, Germany. U.S. Pat. 778,406, Dec. 27, 1904.

A SERIES of horizontal rings having dotted flanges on their outer edges, is arranged upon the central pipe in the bowl of a separator. Radially disposed blades, provided with notches in their inner edges corresponding with the rings and flanges, are arranged round the bowl. The slots in the flanges allow the blades to be readily placed in position or removed.—W. H. C.

Centrifugal Machine. J. C. Morrison, Chicago, Ill., Assignor to United States Peat Fuel Co., Illinois. U.S. Pat. 778,458, Dec. 27, 1904.

A FEEDING screw charges wet material from a hopper, intermittently, into the basket of a centrifugal machine having an open top, and discharge doors in the bottom. After a suitable period, the feed is stopped, the discharge doors are automatically opened, and a scraper, working on the central pillar of the machine, is brought into action to assist in the discharge of the dried material. The whole series of operations is arranged to take place automatically and without stopping the rotation of the basket, the feed being stopped while the discharge doors are opened and *vice versa*. Separate channels are provided for the delivery of the liquid and solid products.—W. H. C.

Rotary Drier. F. A. Wegner and J. D. Bourdeau, Detroit, Mich. U.S. Pat. 779,196, Jan. 3, 1905.

IN drying and cooling apparatus, claim is made for a receptacle B, which can be rotated round a vertical axis relatively to a stationary conduit C, extending downwards into, and concentric with, the receptacle. The conduit is connected with exhaust mechanism as shown, and has circular perforations, as shown, through the sides, and a perforated cap or partition e, between the material and the exhaust. A series of radial projections, at G, extends inwards from the receptacle B, and outwards from the conduit, C. There is also a charging shoot F, at the top, and a valve-controlled outlet passage at the bottom of the receptacle, B.—W. H. C.

Filtering Apparatus for Separating Solids from Liquids.

K. Kiefer, Cincinnati. U.S. Pat. 779,607, Jan. 10, 1905.
SEE Fr. Pat. 325,255 of 1902; this J., 1903, 690.—T. F. B.

Roasting Furnace. F. Klobetko, New York. U.S. Pat. 779,717, Jan. 10, 1905.

THE furnace has a number of superposed hearths, through the centres of which a rotating hollow shaft passes, carrying over each hearth, hollow, radiating arms of special character, each arm communicating by means of an air conduit with a separate chamber in the hollow shaft.—E. S.

Electrically Heated Means for —. S. Hughes, Summerville, S.C., Assignor to E. F. Lowndes, Charleston, S.C. U.S. Pat. 779,833, Jan. 10, 1905.

A PIPE closed at the bottom and made of acid-resisting material, is sunk in a well-casing, and extends upward as high as the supply tank with which it is connected by another pipe. Inside it is placed a delivery-pipe, open at the bottom and communicating at its upper end with a receiving-tank. Compressed air is blown into the lower end of the delivery-pipe, and a valve in the supply-tank controls the flow of liquid.—L. F. G.

Electrically Heated Means for —. S. Hughes, Summerville, S.C., Assignor to E. F. Lowndes, Charleston, S.C. U.S. Pat. 779,941, Jan. 10, 1905.

A LONG vertical pipe open at the bottom stands in a well-casing, and communicates at its upper end with a receiving-tank. A shorter pipe leads from its lower end up to a supply-tank, and is provided with a short vertical pipe open to the atmosphere. Compressed air from a reservoir is blown into the bottom part of the long pipe, and the emulsion of liquid and air discharged into the receiving-tank. (See also preceding abstract.)—L. F. G.

Crystallisation: Method of —. V. Schutze, Riga, Russia. U.S. Pat. 780,448, Jan. 17, 1905.

SEE Fr. Pat. 329,896 of 1904; this J., 1904, 708.—T. F. B.

II.—FUEL, GAS, LIGHT.

Spirit for Lighting Purposes (Carburised Spirit). O. Mohr, Z. Spiritusind., 1905, 28, 11.

THE author shows that, contrary to certain statements, carburised spirit can never compete with petroleum so far as light-giving power is concerned. Most carburised spirits (e.g., those containing naphthalene) contain a carbonaceous constituent which is less volatile than the alcohol, with the result that the carburising substance concentrates at the top of the wick causing smoking and clogging. The lighting power of a fuel is determined by the proportion of carbon the flame is capable of maintaining in the incandescent state, and this depends on the temperature of the flame, as does also the degree of incandescence attained. The heat of combustion of alcohol is, however, only one-half that of petroleum, so that even if the difficulty of clogging were surmounted, the alcohol flame could not carry so much carbon as the petroleum flame, without smoking. On the other hand, alcohol is far more suited for burning with incandescent mantles than petroleum.—J. F. B.

Incandescent Mantle: Theory of the —. V. B. Lewes, J. Gas Lighting, 1905, 89, 161-163.

THE author discusses the various theories which have been propounded to account for the brilliant incandescence of the Auer mantle and expresses himself in favour of the catalytic theory, formerly supported, but now rejected by Bunte (this J., 1904, 1140). That ceria, as it occurs in a mantle, can act catalytically, is shown by the well-known fact that, under proper conditions, a mantle once raised to incandescence, can be kept luminous in a cold stream of coal-gas and air. The fundamental experiments which caused Bunte to discard the catalytic theory consisted in first determining the temperature at various points on the surface of a

naked Bunsen flame, and then, having placed a mantle over it, determining the temperature at the same points as before. The flame was found to be considerably hotter than the mantle at the corresponding points. In the author's opinion, such a comparison is fallacious as the shape, and therefore the temperature, of the Bunsen flame are altered when a mantle is placed over it, and the proportion of air drawn in at the air-hole is reduced. His experiments lead him to the following conclusions. Thoria, owing to its non-conductivity, low specific heat and low heat-emissivity, can acquire the temperature of the flame, whilst catalytic action on the gaseous mixture raises the thoria a few degrees even above this point. Ceria, when added in quantities up to 1.5 per cent. by weight ("or 0.15 per cent. by volume") tends by its still greater catalytic power to localise the combustion on the surface of the mantle, raising the temperature of the particles of ceria to a far higher temperature than the mantle. The addition of more ceria so increases the heat-emissivity of the mantle, that both mantle and flame are cooled by radiation, and the illuminating power falls correspondingly.—H. B.

Cadmium Amalgam Lamp of Quartz. O. Lummer and E. Gehecke. XI. A., page 139.

Coke: Improved Mode of Making —, and Apparatus to be used therefor. T. Settle and W. A. Padfield, Exeter. Eng. Pat. 4708, Feb. 26, 1904.

THE variable density of coke, produced in the ordinary way, is said to be due to charging the coal in bulk. It is proposed to get over this difficulty by charging it in small regulated quantities and at short intervals, thus gradually building up, in the coke-oven, incandescent piles of coke with sloping sides and an outer layer of fresh uncooked coal. The apparatus consists of a conical charging hopper, through which a vertical rod passes, and extends through the vertical passage leading to the oven. Two conical plungers are mounted on this rod at an adjustable distance apart. By imparting a reciprocating vertical motion to the rod, the coal is measured and discharged into the oven.—W. H. C.

Carbon Biocide [from Furnace Gases, &c.]: Manufacture of —. J. C. Stead. Eng. Pat. 18,710, Aug. 30, 1904. VII., page 132.*Tar and other Impurities: Extraction of — from Illuminating Gas.* W. Everitt, Ilkley, and T. Redman, Bolton, Yorks. Eng. Pat. 1826, Jan. 25, 1904.

Electrodes: Arc Lamp —. H. C. Levis, London. From The General Electric Co., Schenectady, U.S.A. Eng. Pat. 4134, Feb. 18, 1904.

THE claims cover arc lamp electrodes consisting of tubes of iron or other metal filled with particles of iron, and closed at one end.—T. F. B.

UNITED STATES PATENTS.

Fuel: Artificial — and Process of Making same. G. W. Herbein, San Francisco, Cal. U.S. Pat. 778,781, Dec. 27, 1904.

THE fuel is composed of a mixture of "alkaline-peat-charcoal" and a partially saponified mixture of petroleum, resin and an alkali. The resin is dissolved in petroleum, an alkali added, and the mixture heated to partial saponification. The peat is rendered alkaline with an alkali and burnt to charcoal. The latter is then mixed with the partially saponified petroleum and resin, and a drier added.—W. H. C.

Oil as Fuel; Means for the Utilization of Crude — J. O. Alwood, Richmond, Va. U.S. Pat. 779,985, Jan. 10, 1905.

THE claim is for a combination comprising a steam superheater coil concentric with a vapour-generator coil, means for supplying oil and steam to these, and a heater common to both coils. The vapour-generator coil is connected to an independent mixing-chamber supplying the heater with gas, and the steam superheater-coil is connected to a radiator.—L. F. G.

Smoking; Process of — A. Custodis, Düsseldorf, Germany. U.S. Pat. 778,846, Jan. 3, 1905.

SEE Addition of Jan. 7, 1903, to Fr. Pat. 305,879 of 1900; his J., 1903, 944.—T. F. B.

Gas; Process of Making — V. G. Apple, Dayton, Ohio. U.S. Pat. 777,829, Dec. 20, 1904.

THIS is a continuous process for the manufacture of coal-gas and enriched water-gas. A constantly-renewed body of carbonaceous material is subjected to dry distillation, while moving through a heated area, and the incandescent coke obtained is quenched in water, the steam generated thereby is mixed with the gas obtained by the distillation, and the mixture is passed through the incandescent coke at a point between the area of distillation and that of cooling the coke.—W. C. H.

Gas-Producer. S. T. Wellman, C. H. Wellman, and J. W. Seaver, Assignors to the Wellman-Seaver Engineering Co., Cleveland, Ohio. U.S. Pat. 778,614, Dec. 27, 1904.

THE producer comprises a rotating body provided with double-chambered outer water-jacket, and having inwardly projecting hollow stirring arms communicating with one of the chambers of the water-jacket, and circulating pipes projecting into the hollow arms, communicating with the other water-chamber, and means for supplying water to one of the chambers, and conveying it from the other. A sealed air-chamber surrounds the outer portion of the body of the producer, and communicates with the inwardly projecting tuyère-boxes carried by the body. The body has upper and lower flanges and sealing troughs, and means are provided for the supply of air, under pressure, to the chamber between the upper and lower sealing troughs.—W. C. H.

Gas; Apparatus for Manufacturing — P. Eyermann, Beloit, Wis., Assignor to J. R. Weninger, Westmont, Pa. U.S. Pat. 779,776, Jan. 10, 1905.

A GAS-PRODUCER is connected by a pipe at its upper part to a gasholder, and by a pipe at its lower part to a second gasholder, the air blast being supplied through a central pipe at the bottom. While the air blast is in operation, the gas produced is led off at the top to the first gasholder; the air blast is then stopped, and the gas is forced back through the incandescent fuel into the second gasholder, for the purpose of fixing the tarry vapours and moisture, and converting the carbon dioxide into carbon monoxide. Two producers may be connected to the same two gasholders, so that the gas generated in the one may be forced down through the incandescent fuel in the other. The connecting pipes are provided with suitable valves for effecting the reversals.—H. B.

Illuminating Gas; Apparatus for Generating — F. J. Foveaux, Alameda, Cal. U.S. Pat. 779,842, Jan. 10, 1905.

A WATER-GAS generator is connected to a tower, the upper portion of which is filled with checker work, and forms a steam-superheater; the middle portion, which constitutes the carburetting chamber, is provided with inlets for superheated steam, oil, and water-gas; and the lower portion, forming the initial fixer, is filled with checker work and connected at the foot to a supplementary fixer. The latter has an inlet pipe for oil fuel and an outlet pipe for finished gas, at its upper end, and is connected at its lower end to the initial fixer.—H. B.

Gas-Producer. J. A. Herrick, Philadelphia, Pa. U.S. Pat. 779,935, Jan. 10, 1905.

A GAS-PRODUCER is claimed, having a blast-pipe extending across its base, this pipe having one end connected with a blower, and the other end provided with a check-valve. The hopper of the gas-producer has parallel pipes extending into and through it, and these pipes are provided with blast-ports, which discharge within the hopper.—L. F. G.

Gas-Producer. W. J. Crossley and T. Rigby, Manchester. U.S. Pat. 780,090, Jan. 17, 1905.

SEE Fr. Pat. 341,970 of 1904; this J., 1904, 897.—T. F. B.

FRENCH PATENTS.

Agglomerate [Briquettes] of the "Charbon de Paris" Type; New —, and Process of Manufacturing it. F. A. Cardot. Fr. Pat. 339,173, Nov. 19, 1903.

POWDERED charcoal, chalk, and dextrin are intimately mixed together in suitable proportions, and steamed. The mass is then moulded into briquettes and dried. A suitable composition is stated as being: 10 parts of chalk, 0.5 part of dextrin, and 89.5 parts of charcoal.—L. F. G.

Gas-Producer [Suction]. P. Lamare. Fr. Pat. 346,142, Sept. 9, 1904.

THE fuel in the producer rests on a solid hearth of refractory material, which can be oscillated by means of an external handle, for the purpose of loosening the fuel. A boiler, for supplying the steam required by the producer, is placed in the path of the hot gases between the producer and the scrubber. The latter is built up of superposed, interchangeable, short cylindrical sections provided with horizontal plates having devices for breaking up the current of gas as it ascends through the water flowing down over the plates. At the top of the scrubber the washed gas enters a chamber fitted with a spiral partition, which acts as a centrifugal purifier. The apparatus is characterised by detail modifications in the construction of the fuel hopper, the boiler feed, sight-holes, starting pump, &c. The outer limb of the syphon pipe, which admits the water to the scrubber, is of large diameter, to prevent air bubbles being dragged in, thus diluting the gas.—H. B.

Gas-Purifier [Vertical]. Soc. Anon. des Ateliers de Montreuil. Fr. Pat. 346,140, Sept. 8, 1904.

THE purifier, which is adapted for purifying coal-gas, is arranged vertically instead of horizontally, each section consisting essentially of a gas-tight vertical chamber divided longitudinally into three compartments by means of two vertical partitions constructed of louvres. The middle compartment is filled with the purifying material, the louvres serving to keep the material in position whilst permitting the free passage of the gas from one of the outer compartments, through the purifying material, into the other outer compartment. The spent purifying material is discharged when necessary by withdrawing a plug at the bottom of the chamber. Horizontal baffle plates in the outer compartments cause the gas on entering to be distributed over the whole surface of the screen of purifying material. The sections are grouped together in any desired manner. Charging takes place from a staging above the vessels.—H. B.

Filament; An Indestructible — for Heating and Lighting Purposes. G. Michand and E. Delasson. Fr. Pat. 346,307, Sept. 17, 1904.

FINELY powdered magnesia, silica, lime, or alumina is fed through the central tube of an oxy-hydrogen blow-pipe on to a support made of alumina carried on the top of a screwed shaft. The material melts, and by gradually screwing back the support, a filament is produced. The uniform distribution of the material is ensured by an electric tapping arrangement.—L. F. G.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

Petroleums, Compt. rend. — M. Weger. *Chem. Ind.*, 1905, 28, 24—29.

A NUMBER of commercial burning oils of American, Russian, Roumanian, Galician and German origin, were examined for their physical properties and composition, and the results are expressed in a number of tables together with a diagram of curves, indicating the percentages of constituents of various boiling points.

The specific gravity, ranging from 0.7905 to 0.8255, depends in part on the boiling point, and also on the chemical composition of the oil, *i.e.*, the ratio between the paraffins, naphthenes and olefine group (with which are included the benzene and partially hydrated cyclic bodies), high sp. gr. and low boiling point indicating a large proportion of olefines, and also an inferior oil.

The flashing point, with the exception of two admittedly under-test oils, was equal to the German standard (21° C.), and in most cases to the Austrian standard (28° C.).

To determine the boiling points, the continuous system of distillation (Frank apparatus), employed in testing benzene, was preferred to the Engler intermittent method, being quicker, equally accurate and enabling the results to be expressed graphically, thus facilitating comparison. The copper still is preferably lowered half way into the

heating furnace, to facilitate distillation of the higher fractions; and the temperature at which the first drop are discharged from the condenser, is regarded as the initial boiling point. The volume of distillate is read off at intervals of 10°, and distillation is carried up to the point at which 90 per cent. (vol.) distils over. The results are expressed in the diagram, and in conjunction with the sp. gr., as shown in the following table, furnish pretty clear idea of the properties of the oils.

Number of Oil in Diagram.	Oil.	Limits of b.p.	Sp. Gr. at 15° C.
(1)	Urania (American)	155°-298° C	0.7905
(2)	Nobel (Russian)	143°-289° C	0.8190
(3)	Meteor (Russian)	141°-247° C	0.8000
(4)	Aurora (Roumanian)	138°-239° C	0.8100
(5)	Lipinki "salon" oil (Galicia)	136°-336° C	0.8255
(6)	Gorlice "export" oil (do.)	135°-316° C	0.8155
(7)	German oil from Wietze	135°-270° C	0.8050
(8)	Danubia (Roumanian)	135°-284° C	0.8102
(9)	Gorlice "salon" oil (Gal.)	134°-316° C	0.8200
(10)	Lipinki "export" oil (do.)	133°-323° C	0.8165
(11)	Edelweiss (Roumanian)	130°-268° C	0.8063
(12)	Standard white (American)	125°-332° C	0.8015
(13)	Gorlice "under-test" oil (Gal.)	105°-316° C	0.7925
(14)	Lipinki "inflammable" oil (do.)	82°-343° C	0.8120

From the curves of the two Galician "under-test" oil it appears that whilst that from Gorlice is rich in light spirit ("benzene"), and therefore dangerous, the Lipinki "inflammable" oil is merely a mixture of light fraction ("benzene") and "solar" oil, without any true burning oil fractions.

The variation of the coefficient of refraction is approximately parallel with that of the sp. gr. of the oils.

The method adopted for determining the percentage of the olefines was that of Kraemer and Böttcher, *viz.*, by agitating 25 c.c. of oil with an equal volume of pure sulphuric acid for 15 minutes in a globular flask fused on to a burette, filling up the flask with acid at the end of 30 minutes, and reading off the volume of paraffins and naphthenes displaced into the burette. The smallest percentage is found in American and Russian oils, the largest in those from Galicia and Roumania. The proportion in fractions of equal boiling point can be estimated from the sp. gr. of the paraffins plus naphthenes.

Tests of the illuminating power with a 12" Schuster and Baer burner showed that in point of consumption of oil per candle hour, the American oils are surpassed by several Russian, Galician and German oils, the figures being Meteor (Russian), Lipinki "export" oil, and Gorlice "export" oil, 3.0 grms. per Hefner candle hour; German Nobel and Gorlice "salon" oil, 3.1 grms.; Urania (American), Aurora (Roumanian) and Edelweiss (Roumanian), 3.2 grms.; Danubia (Roumanian) and Lipinki "salon" oil, 3.3 grms.; Standard white oil, 3.4 grms. With regard to the colour of the flame, however, different results were obtained and in this respect the proportion of members of the olefine group seems to have a direct influence in reddening the light, as is shown by the following figures, the whites flame coming first:—Urania (olefine content 10.7 per cent.), Standard White (14.6 per cent.), Meteor (10.4 per cent.), German oil (16.2 per cent.), Nobel oil (12.2 per cent.), Galician oils (22.24 per cent.), Aurora (24.0 per cent.), Edelweiss (21 per cent.), Danubia (22.0 per cent.). The naphthenes also have a certain influence in the same direction. Moreover, on eliminating the olefines from the red-burning oils by washing with a large amount of sulphuric acid, the residual oil gave a white flame. Owing to the large proportion of heavy hydrocarbons in the Lipinki "salon" oil and Standard white oil, a considerable decrease in illuminating power was observed towards the close of the tests.—C. S.

Hydanes; Iso — in Roumanian Petroleum. P. Poni and N. Costachescu. *Annal. Scient. de l'Univ. de Jassy*, 1904, 3, 95—102. *Chem. Centr.*, 1905, 1, 217.

THE fractions of Roumanian petroleum boiling between 59.5° and 64.5° C. consist of 2-methyl- and 3-methylpentane. The former has the sp. gr. 0.6765 at 0°/0° C.

1-Methylpentane when heated with nitric acid of sp. gr. 1.4 in a sealed tube at 60° C. is converted into 3-nitro-3-methylpentane, together with a small quantity of a linitro-compound, and can in this way be separated from 2-methylpentane. (See also this J., 1903, 20.)—A. S.

Phenol; Determination of — S. J. Lloyd. XXIII, page 155.

UNITED STATES PATENTS.

Retort [Wood Distillation]. J. C. Mallonee, Charlotte, N. Carolina, Assignor to J. J. Mallonee, Crichton, Ala. U.S. Pat. 774,261, Nov. 8, 1904.

Two cylindrical horizontal retorts are arranged side by side, and each covered with a smoke cap (arch), standing on a furnace built underneath. The furnace is divided into two parts by a central brick wall extending transversely from end to end, and extending into the smoke caps. Flues are arranged longitudinally along the sides of the retorts for conveying the hot furnace gases. In the destructive distillation of the wood, the gases escape by a pipe at the top of each retort, whilst the tar settles down and is discharged through an outlet at the lower part of the retort.—L. F. G.

Bituminous Material, Crude; Distillation and Treatment of — H. W. Ash, Cambridge, Mass., Assignor to Warren Bros. Co., Boston, Mass. U.S. Pat. 779,197, Jan. 3, 1905.

CRUDE bituminous material is heated in a still to about 300° F., and at the same time subjected to a blast of hot air carrying finely-divided matter such as lampblack, in order to force this into the distillate, the mixture being cooled suddenly by a cold blast.—A. G. L.

Bituminous Material; Method of Distilling Crude — H. W. Ash, Cambridge, Mass., Assignor to Warren Bros. Co., Boston, Mass. U.S. Pat. 779,198, Jan. 3, 1905.

THE bituminous material within a still is subjected to the action of a heated blast on the outside of it; at the same time the products of combustion which have passed the outside of the still are introduced under pressure into the interior. The hot blast may be charged with finely divided solid matter, such as lampblack.—A. G. L.

FRENCH PATENTS.

Hydrocarbons; Process for Producing —, and for Eliminating the Sulphur from Hydrocarbons and Petroleum containing it. H. S. Blackmore. Fr. Pat. 346,275, Sept. 15, 1904.

PETROLEUM or other hydrocarbon containing sulphur is purified by passing it, in a state of vapour, over a mass of heated metallic or alkaline-earth carbide, which treatment results in the formation of metallic or alkaline-earth sulphide and a hydrocarbon or mixture of hydrocarbons; e.g., by starting with dimethyl sulphide, a mixture of ethylene and acetylene is produced. This treatment is also applicable to removing sulphur compounds from coal gas. In place of using a carbide, acetylene may be used; or the hydrocarbon vapour mixed with steam, may be passed over the heated carbide. After the treatment, the hydrocarbon is preferably agitated with an "oxide or metallic base" to further purify it, and then it is distilled with steam.—T. F. B.

IV.—COLOURING MATTERS AND DYESTUFFS.

Diazobenzene and Aniline; Limit of Combination of — L. Vignon. Comptes rend., 1905, 140, 91—93.

THE author endeavoured to combine one mol. proportion of diazobenzene chloride with one of aminoazobenzene in presence of one of potassium carbonate, under various conditions, but without success. By the action of the chloride of diazotised aminoazobenzene on aniline

in presence of potassium carbonate a compound is obtained at 0° C., diazoaminoazobenzene was formed, according to the equation:—

The yellow product may be crystallised at 0° C. By the action of a mixture of aniline and nitrobenzene chloride it is converted, after 24 hours' action, into aminoazobenzene, according to the equation:

The author remarks that Nietzka and Diesterweg obtained a very small amount of a more complex product from this reaction in the form of the acetyl compound $\text{C}_6\text{H}_5\text{N}_2\text{C}_6\text{H}_4\text{N}_2\text{C}_6\text{H}_4\text{NHCOCH}_3$. Attempts to obtain aniline bisdiazobenzene ($\text{C}_6\text{H}_5\text{N}_2\text{C}_6\text{H}_4\text{N}_2\text{C}_6\text{H}_5$) by the action of one mol. of diazobenzene chloride on diazoazobenzene and by the action of two mols. of diazobenzene chloride on aniline, failed. This substance is formed, however, by the action of two mols. of nitrosoacetanilide on one mol. of aniline in presence of caustic alkali, according to the equation:—

This substance forms yellowish-orange needles, is unstable, and detonates on warming. On heating for 24 hours at 40° C. with aniline and aniline hydrochloride it is transformed into aminoazobenzene, which seems to represent the stable limit of the azo compounds derived from diazobenzene and aniline.—E. F.

Methylene Blue; Determination of — E. Kuecht. XXIII, page 154.

Indigo White; Manufacture of — J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. Eng. Pat. 6226, March 14, 1904.

INDOXYL and indoxylie acid are oxidised by indigo to indigo white, the indigo being simultaneously reduced to the same substance. The speed of the reaction is increased

by the addition of an oxygen carrier, such as a salt of iron or an alkali sulphite. It is not necessary to isolate the indoxyl or indoxyllic acid, as the alkaline melt obtained during their manufacture may be employed directly in aqueous solution. It is also unnecessary to use indigo which has been prepared beforehand, as the indoxyl or indoxyllic acid may be partially oxidised by air or any other oxidising agent to indigo, and this indigo then allowed to react with the remaining indoxyl or indoxyllic acid. The alkaline indigo white solution, which results by any of these methods, may be filtered from any unchanged indigo, and the indigo white can then be precipitated by acids or by carbon dioxide. — E. F.

Azo Colouring Matter [Dyestuff] and Lakes therefrom: Manufacture of —. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. Eng. Pat. 6839, March 21, 1904.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

Silk; Artificial —. Bull. of the Imperial Inst. (Suppl. to the Board of Trade J.), 1905, 2, 266–269.

THE physical properties of the artificial silks produced by the various processes at present in use are very similar, but are inferior to those of natural silks, their elasticity and tenacity, especially when wetted, being considerably lower on the whole. Appended are the results of some tests of breaking stresses, given in kilos. per sq. mm. :—

	Breaking Stresses.	
	Dry.	Wet.
NATURAL SILKS—		
Chinese	53.2	46.7
French, raw	50.4	40.9
French, boiled off	25.5	13.6
ARTIFICIAL SILKS—		
De Chardonnet "collodion," undyed	14.7	1.7
Lehmer's "collodion," undyed	17.1	4.3
"Viscose" (early samples)	11.4	3.5
"Viscose" (latest samples)	21.5	—

Samples of cotton yarn gave results of 11.5 and 18.6 kilos. respectively. — T. F. B.

"Noir Réduit": Preparation of —. E. Lauber. Z. Farben- u. Textil-Ind., 1905, 4, 40.

72 KILOS. of logwood extract Ia. (53° T.) are stirred with 12 litres of acetic acid (16° T.) until the solution is quite homogeneous. 5400 grms. of potassium bichromate, finely powdered, are made into a paste with 1.2 litres of boiling water. 18 litres of acetic acid (16° T.) added, and the whole brought slowly to the boil with constant stirring. When all is dissolved, it is poured, half a litre at a time, into the logwood solution with vigorous stirring, in order to prevent the oxidised hæmatein which separates out from forming large lumps. After stirring about 1 hour longer, a mixture of 18 litres of sodium bisulphite solution (57° T.) with 8 litres of water, is added 2 litres at a time, with vigorous stirring, the stirrer is then taken out and the vessel well covered. From hour to hour it is inspected to see whether crusts have formed on the surface. If this is so, they are passed with a strong brush through a coarse hair sieve and then replaced in the vessel. From time to time a drop of the mixture is examined on a glass plate; if it is bright olive coloured to transmitted light, the product is good. It is ready for immediate use after passing through a fine sieve. — A. B. S.

Formic Acid; Use of —, in *Dyeing and Printing*.
S. Kapff. *Färber-Zeit.*, 1904, 15, 357–361.

Wool Dyeing.—Formic acid may be used in all cases where, on account of irregular absorption of a dyestuff from a bath containing sulphuric acid, acetic acid or ammonium acetate has been hitherto adopted as a more suitable assistant to the dyeing. It is said to cause a larger proportion of dyestuff to be taken up by the wool; to enable the after-rinsing to be accomplished readily and effectually; and, unlike acetic acid, to leave the dyed material free from objectionable smell. Again, in applying dyestuffs to wool mordanted with chrome, the addition of formic acid to the dyebath is said to cause an increased proportion of dyestuff to become combined with the mordant and more intense dyeings to result.

Dyeing Woolen Tissues with Woven Silk Effects.—These are frequently so dyed that the silk remains undyed, or is dyed differently from the wool. The following dyestuffs, possessing as they do greater affinity for wool than for silk, are serviceable for producing such effects:—Alizarin Sapphirol (Bayer), Naphthol Green B (Cassella), Azo Fuchsin G (Bayer) (the red dyeings from this may be converted by after-chroming into black), Fast Yellow S (Cassella). From a sulphuric acid bath, these dye both fibres, but the silk less deeply than the wool. When acetic acid, or, in some cases, oxalic acid is used, more satisfactory results are obtained, especially if the tissues, after dyeing, are treated with bran or ammonium acetate, to clear the silk, but much dyestuff is left in the bath. By the substitution for these acids of formic acid, the dyebaths are caused to become completely exhausted, the silk being more deeply coloured than it is with acetic acid, but less so than with sulphuric acid. The use of formic acid is to be recommended when the silk is afterwards to be dyed in a different colour from that in which the wool has first been dyed.

Mordanting Wool with Chrome.—This is the most important application of formic acid in dyeing. With $\frac{1}{2}$ per cent. (of the weight of the wool) of potassium bichromate and $\frac{1}{2}$ per cent. of formic acid (85 per cent.), the chromic acid is not only liberated, but completely reduced, and the resulting chromic oxide is wholly fixed upon the wool, after $1\frac{1}{2}$ hours' boiling, a stronger mordanting being effected than that produced with 3 per cent. of potassium bichromate and 2½ per cent. of tartar. It is stated that so perfectly is the chromium absorbed that in the case of loose wool, the bath may be afterwards employed as a dyebath, the wool so mordanted and dyed, spinning very regularly and easily. The deepest shades ordinarily required upon woollen materials are obtained upon a mordant produced from about 2 per cent. of potassium bichromate and 2 per cent. of formic acid solution (85 per cent.), a little more of the latter being taken, when necessary, in order to counteract the influence of the dissolved salts, when "hard" water is used in mordanting. The dyeings obtained on the wool mordanted in this manner are very fast to milling and to rubbing.

Formic acid may also be advantageously applied along with chromic acid or potassium bichromate to complete the after-chroming of dyed tissues. As the whole of the chromium is thus caused to be absorbed, the bath may be preserved for use again in dyeing. Chromium formate is not suitable for the purpose.

Cotton Dyeing.—The acid may be used to give a seroopy silk-like feel to mercerised cotton tissues, for which purpose acetic acid is valueless, sulphuric acid dangerous, and citric and tartaric acids too expensive.

Silk Dyeing and Finishing.—Formic acid is very suitable for use in dyeing and brightening silk tissues.

Calico Printing.—With printing mixtures containing Methylene Blue, Auramine and Magenta, formic acid is found to give paler and brighter shades than acetic acid. In resisting Aniline Black, sodium formate is capable of replacing double its weight of sodium acetate.

Waterproofing Tissues.—Aluminium formate because of the ease with which it decomposes is especially suitable for this purpose. The tissues are passed through a solution of the salt and dried; they may be afterwards treated with a boiling soap bath to increase their impermeability.

Antiseptic Properties. A sample of stain-proof material containing 5 per cent. of the acid, remained unchanged a long time after a second sample made with it, the acid had become watery and decomposed. See A. G. Green and A. B. Steven, this J., 1904, 111, 1. E. R.

Fastness to Perspiration; Tests for —, P. Heilmann. *Färber-Zeit.*, 1905, 16, 21–22.

A CRITICISM of an article by Davidis (this J., 1905, 8). The author shows that Davidis' method often indicates results which are not in accord with practical experience. See A. B. S.

ENGLISH PATENTS.

Revolving Kier (for Treatment of Textile Fibres, &c.) —, J. Singleton, Manchester. Eng. Pat. 4552, Feb. 24, 1904.

AN "oblong hollow cylinder" is supported axially by a hollow perforated shaft mounted in suitable bearings. The cylinder is divided lengthwise into four or more equal compartments, by means of perforated partitions; these compartments are also provided with perforated false ends. Each compartment is fitted with a door for filling with the material and with a valve for letting out the liquid. The whole cylinder is mounted so as to revolve slowly in a cistern, and liquid is forced through the perforations of the central shaft by means of a suitable pump. This passes through the material and out through the outlet valves.—A. B. S.

Dyeing or Charging Silk with Tin Compounds. —, F. W. Howarth, London. From Soc. Anon. Coop. per la Stagionatura e l'Assaggio delle sete ed' Affini, Milan. Eng. Pat. 25,728, Nov. 25, 1904.

To prevent the tendering of leaded silk, it is treated during the operations of charging, clearing or dyeing, with a solution of 0.5–3 per cent. of sulphocyanic (thiocyanic) acid or one of its salts.—A. B. S.

Textile Fibres, Bags, Bares, &c.; Composition for Impregnating [Water and Oil-Proofing] —, F. Duschek and L. Witte, Bucharest. Eng. Pat. 24,482, Nov. 11, 1904.

10 KILOS. of argillaceous earth are mixed with 2 kilos. of red lead and 3 kilos. of glycerin. The mixture is thoroughly ground up, and a 40–50 per cent. gelatin solution containing 50 kilos. of gelatin is added hot, together with 10 grms. of salicylic acid, 0.5 kilo. of soda-alum, and 2 kilos. of common salt. The whole mass is then boiled, cooled down to 30° C., and 0.2 kilo. of ammonium chromate added. The material is applied at once to the bag or other object, and after drying, treated with a solution of tannin and chrome alum to make the gelatin insoluble. The coatings formed are stated to be quite impermeable to liquids and perfectly flexible, and remain intact even if the receptacle itself be damaged.—A. B. S.

UNITED STATES PATENTS.

Silk-like Thread; Manufacture of —, R. Müller, Assignor to Farbwerke vorm. Meister, Lucius und Brüning, Höchst-on-the-Maine, Germany. U.S. Pat. 779,175, Jan. 3, 1905.

SILK-LIKE threads are manufactured by forcing alkaline

solutions of "cellulose ammonium" through capillary tubes, into caustic alkaline solutions, washing the "wound-up threads" thus formed successively with acids and water, and subsequently drying.—T. F. B.

Fabrics; Apparatus for Treating — with Fluids. J. Gebauer, Charlottenburg, Germany. U.S. Pat. 779,976, Jan. 3, 1905.

SEE Eng. Pat. 21,949 of 1903; this J., 1904, 932.—T. F. B.

Dyeing; Process — H. Mann, Munich, Germany. U.S. Pat. 779,228, Jan. 3, 1905.

Dyeing Machine. J. A. Willard, Assignor to Vacuum Dyeing Machine Co., Chattanooga, Tenn. U.S. Pat. 780,398, Jan. 17, 1905.

IS the centre of the dye-vat, which is cylindrical in form, is an overflow pipe of large diameter, extending nearly to the top of the vat. A perforated plate to support the goods to be dyed, and a perforated compression plate are provided in the vat, with suitable arrangements for removing and replacing these plates. Within the overflow pipe is situated a pipe with perforated end, connected with a pump, which removes the overflowing liquor, and pumps it again through a supply pipe which feeds a number of pipes which enter the dye-vat beneath the supporting plate, thus maintaining a circulation of the liquor.—T. F. B.

Dyeing; Apparatus for — J. A. Willard, Chattanooga, Tenn. U.S. Pat. 780,399, Jan. 17, 1905.

THE dye-vat is cylindrical in form, and is composed of a number of shallow flanged sections jointed together, so that the capacity of the vat can be increased or diminished as desired. In the base of the vat, and extending below it, is a casing containing a centrifugal pump; two or more pipes for circulating liquid are connected on the one hand with the casing, and on the other hand with the top of the dye-vat. Steam pipes are provided for heating the contents of the vat and also the liquor supply pipes. Perforated supporting and compression plates are provided in the vat, with suitable mechanism for operating them.—T. F. B.

Dyeing, &c.; Vat for — J. A. Willard, Assignor to Vacuum Dyeing Machine Co., Chattanooga, Tenn. U.S. Pat. 780,402, Jan. 17, 1905.

THE overflow openings of the dye-vat, which are situated close to the top of the vat, are connected with small receptacles, which are provided with filters and outlet pipes connected with a pump, and also with a number of vertical rods, which carry "locking dogs" to keep the perforated compression plate in position in the vat. The lower face of the compression plate and the upper face of the fibre-supporting plate are coated with some metal which is not affected by alkaline liquors. Other claims relate to a special form of strengthened compression plate, and to devices for holding it in position in the vat.—T. F. B.

Fabric; Figured — J. Morton, Carlisle. U.S. Pat. 779,300, Jan. 3, 1905.

SEE Eng. Pat. 18,897 of 1903; this J., 1904, 932.—T. F. B.

Waterproofing and Process of Making same. H. Paschke, New York. U.S. Pat. 780,379, Jan. 17, 1905.

TWO sheets of fabric are coated with a waterproofing composition consisting of bitumen or asphalt and "the gummy products of the refinement of petroleum," and the treated faces are united by means of a solution of the same waterproofing compound in a suitable solvent.—T. F. B.

Wool-wash Waters; Apparatus for Treating [Separating Fat from] — G. E. Behrens and G. Taylor. U.S. Pat. 780,475, Jan. 17, 1905. *N.H.*, page 141.

FRENCH PATENTS.

Benzene used for Dry Cleaning Fabrics; Process and Apparatus for Recovering the — E. Delhotel. First Addition, dated Sept. 6, 1904, to Fr. Pat. 344,848, July 16, 1904.

THE addition relates to certain improvements in the apparatus described in the principal patent (this J., 1904, 1213), with the object of accelerating the operation. For example, two drying chambers are employed, and are connected together and with the air and vacuum pipes by means of valved pipes, one of the chambers being in use while the other is being emptied or re-filled. Devices are also described for suspending the goods which have been cleaned, in such a way as to obtain more rapid and even removal of the benzene.—T. F. B.

Dyeing Yarns; Process for —, enabling them to be Treated by the Processes and in the Apparatus used in Dyeing Fabrics. Soc. L. Destrée, A. Wiescher et Cie. Fr. Pat. 346,256, Aug. 2, 1904.

SEE Eng. Pat. 17,240 of 1904; this J., 1904, 1087.—T. F. B.

Discharging [Dyed Textiles] by means of Hydrosulphites; Process of — Badische Anilin und Soda Fabrik. Second Addition, dated Sept. 17, 1904, to Fr. Pat. 297,370, Feb. 19, 1900. Under Internat. Conv., June 27, 1904.

INSTEAD of adding a concentrated solution of caustic alkali to the discharge mixture, as described in the First Addition (see this J., 1905, 87), saturated solutions of certain salts may be used. Thus, a fabric printed with a mixture of dyestuff, sodium hydrosulphite and sodium chloride can be dried for several hours at 100° C. without the hydrosulphite losing its discharging properties.—T. F. B.

Finishing Material; Preparation of a — [from Molasses, &c.] M. Kowalski. Fr. Pat. 346,355, Sept. 19, 1904.

MOLASSES or similar by-product from the manufacture of sugar is run into water at 50–60° C., and the mixture is immediately submitted to the action of sulphuric acid in an acid-resistant vessel until it gives a strongly acid reaction; at the same time the mixture is kept well stirred and a metallic powder, such as zinc, aluminium or tin, is added. The mixture is heated to 50–70° C. If the liquid has a clear yellow colour, more metallic powder is added, and the mixture is treated with sulphuric anhydride or chlorine until the acidity attains a certain point. The liquid is passed through a filter press and thickened by evaporation. The filtrate is finally neutralised by means of carbonates. It forms a clear yellow syrup very suitable for finishes.—A. B. S.

VI.—COLOURING WOOD, PAPER, LEATHER, &c.

Dyeing of Leather, &c.; New Processes for the — Sedlacek. *Färber-Zeit.*, 1905, 16, 17–20.

THE sulphide dyestuffs can be applied to leather by the addition of glucose or tannin to the dye-bath, which prevents the injurious action of the sodium sulphide on the leather. The dyings can be treated afterwards with bichromate or other metallic salts. The glucose may be replaced by formaldehyde. Very fast yellow and brown shades can be obtained by soaking the tanned leather several hours in a solution of a titanium salt. Titanium salts can also be used as mordants for the various dye-woods. Very fast shades are obtained by tanning with dye-wood extracts mixed with other tannin materials, and then treating with titanium salts. For hair dyeing, water or alcoholic solutions of many substances such as *p*-phenylene-diamine, *p*-aminophenol and *p*-diaminodiphenylamine are used. On exposure to the air or by the action of oxidising agents such as hydrogen peroxide, these substances give brown oxidation products of various shades according to the choice and strength of the solutions.—A. B. S.

VII.—ACIDS, ALKALIS, AND SALTS, AND NON-METALLIC ELEMENTS.

Chamber Process; Theory of the — G. Lunge. Z. angew. Chem., 1905, 18, 60—71. (See this J., 1904, 440, 924, 1178, 1213.)

ASCHIG denies that the nitrous character of the chamber acid is due to nitrosylsulphuric acid, and holds that the chamber acid merely contains dissolved nitrogen trioxide. Solutions of nitrous acid in water or weak sulphuric acid are, however, exceedingly unstable, whilst the nitrous compounds contained in the chamber acid are very stable. Aschig also refers to the small amount of nitrogen trioxide in chamber acid (0.03 per cent. of N_2O_3 equiv. to say 1 per cent. of nitrosylsulphuric acid), but the author points out that 0.1 per cent. of nitrosylsulphuric acid would mean 100 kilos. in a set of chambers producing 2000 tons of chamber acid, even if there were none in the chamber cloud. The author found that the chamber acid and the "drop-acid" from the Uetikon Works, at Zürich, contained respectively 0.085 and 0.24 per cent. of nitrosylsulphuric acid. Raschig's statement that when nitric oxide and excess of air are shaken with water, nitrous acid, as well as nitric acid, is produced, never more than half the nitrogen being converted into nitric acid, has no bearing on the chamber process, where practically no nitric acid is formed at all; but, as a matter of fact, the author and others (this J., 1905, 88) have shown that the enormous excess of water present in Raschig's experiments alters the reaction fundamentally, and that under other conditions, practically the whole of the nitric oxide present is converted into nitric acid. — J. T. D.

Alkali Oxides; Affinity of — for Different Anhydrides. D. G. Gerassimoff. Z. anorg. Chem., 1904, 42, 329—340.

WITH a view to determine the conditions of equilibrium between alkali oxides on the one hand, and volatile and non-volatile anhydrides on the other hand, the author examined: (1) The action of sulphur trioxide on fused alkali tungstates and vanadates; and (2) the action of carbon dioxide on alkali tungstates, vanadates, niobates, tantalates, titanates and aluminates. (1) In most of the experiments equilibrium was attained from two different starting points, viz., by passing air containing a definite proportion of sulphur trioxide over the fused alkali tungstate or vanadate; and by fusing a mixture of

tungstic or vanadic anhydride and sulphur trioxide was prepared by passing air through a heated U-tube containing the anhydride impregnated with fused pyrocarbonate, the experiments with carbon dioxide being conducted with or without the passing of a current of sulphur trioxide. The results of the experiments in conjunction with those previously obtained by D. P. Smith (Z. anorg. Chem., 1903, 37, 332) and N. M. von Witten (ibid., 1904, 40, 103) show that the affinity of an alkali oxide for carbon dioxide or sulphur trioxide increases with its molecular weight in all systems in equilibrium in which the following pairs of anhydrides participate: Carbon dioxide with silicic, titanitic, tungstic or vanadic anhydride, and sulphur trioxide with tungstic or vanadic anhydride. Vanadic anhydride expels a greater proportion of sulphur trioxide from alkali sulphates than tungstic anhydride. The molecules of carbon dioxide expelled by 1 molecule of the different non-volatile anhydrides from 2 molecules of carbonate at 880° C. under a partial pressure of carbon dioxide of 0.07 atmosphere are given in the following table:

V_2O_5	Nb_2O_5	SiO_2	WO_3	$Al_2O_3^*$	TiO_2	$Ta_2O_5^*$
2.000	1.891	1.319	1.047	1.019	0.779	0.727

*In these cases the anhydride was only partially dissolved in the melt. — A. S.

Ammonia; Formation of — from Nitrogen and Hydrogen. F. Haber and G. van Oordt. Z. anorg. Chem., 1905, 42, 111—115.

A CURRENT of pure ammonia was led over finely-divided iron kept at a temperature near 1000° C. the decomposition products were freed from the undecomposed ammonia by means of standardised acid, then led over a further quantity of heated finely-divided iron, and the amount of ammonia re-formed determined. The iron was prepared from iron oxalate in a current of ammonia, and was supported on asbestos in the heating tube. Some experiments were also made with finely-divided nickel supported on silicic acid (prepared by impregnating silicic acid with nickel nitrate and igniting in a current of hydrogen), but this metal proved a less effective catalyst than iron. The results obtained (see table) show that equilibrium is attained from both sides:—

	Contact Metal.	Residual Gas (at 0° C and 760 mm.) consisting of $\frac{1}{2}N_2 + \frac{1}{2}H_2$.	Parts of Ammonia decomposed per 1000.	Parts of Ammonia formed instead of 1000.	Temperature in 0° C.
		litres.

*Lower temperature at the beginning of the experiment.

†In experiments 1, 2, 8 and 9, the two tubes containing the catalyst were arranged in the same heating tube, but in experiments 3, 4, 5, 6 and 7, two heating tubes were used; the figures in brackets give the variation of the temperature of the second tube from that of the first.

(See also this J., 1904, 915.) — A. S.

Nitric Oxide together with Nitrogen Peroxide; New Method for the Preparation of — J. Matuschek. Chem.-Zeit., 1905, 29, 31.

THE author states that in the preparation of nitric oxide, a more regular evolution of gas is obtained by acting upon an alkali nitrite with an aqueous solution of an iron salt, than by the usual method of treating copper turnings with nitric acid. For example, sodium nitrite is treated with an aqueous solution of ferric chloride. A mixture of nitric oxide and nitrogen peroxide is evolved, but on passing through water the nitrogen peroxide is decomposed into nitric acid and nitric oxide. The reactions taking place are represented by the following equations:—

Carbon Dioxide (from Furnace Gases, &c.); Manufacture of —. — J. C. Stead, London. Eng. Pat. 18,710, Aug. 30, 1904.

THE washed and cooled furnaces or other gases containing carbon dioxide are passed through a series of vertical cylinders ("bicarbonators") charged up to near their tops with a solution of an alkali carbonate. The gases enter each cylinder below a perforated false-bottom, and leave at the top; the exhausted gases finally escape through a pipe which condenses and returns to the cylinder any vapour carried off. The cylinders are connected in pairs by syphon tubes, adapted to automatically circulate the lye in the reverse direction to the flow of gases. The first "bicarbonator" of the series communicates with a "boiling off" vessel at a lower level, into which the bicarbonated lye passes by gravity through pipes provided at their bends with suitable back-pressure valves; and when the absorbed carbon dioxide is expelled from the liquor in the boiler, the decarbonated lye is driven up by steam pressure into the last "bicarbonator" of the series, the original charge having been siphoned off during the charging of the "boiling off" vessel. — E. Lead Silicofluoride; Process of Making. — W. Mills, London, Assignor to A. O. Granger, Cartersville, Ga. U.S. Pat. 779,091, Jan. 3, 1905.

GALENA, or a mixture of galena and cerusite, or other substance containing lead, is heated with hydrofluosilicic acid of about 1.80 sp. gr., air being blown through during the reaction. Water is then added to the resulting lead silicofluoride. — E. S.

Lead Silicofluoride; Process of Making. — W. Mills, London, Assignor to A. O. Granger, Cartersville, Ga. U.S. Pat. 779,092, Jan. 3, 1905.

PURE lead silicofluoride is obtained by heating an oxygen-carrying lead compound, or a corresponding hydrated compound, with an excess of hydrofluosilicic acid, with stirring. More of the lead compound is then continuously added until the acid is neutralised, and the solution is filtered. — E. S.

Sodium Acetate; Process of Making. — I. P. Löhme, Assignor to the Grasselli Chemical Co., both of Cleveland, Ohio. U.S. Pat. 779,290, Jan. 3, 1905.

A SLIGHT excess of sodium sulphate crystals is added to a heated solution of calcium acetate; sufficient barium carbonate is then added to react with the dissolved sulphates and "to adhere to the organic matter," and the solution is concentrated while currents of air are injected to oxidise the organic impurities. The cleared solution of sodium acetate is then crystallised. — E. S.

Chromate of Soda; Method of Treating Alkaline Solutions of —. — W. T. Gibbs, Buckingham, Canada, Assignor to the National Electrolytic Co., N. Y. U.S. Pat. 779,705, Jan. 10, 1905.

THE alkaline solution of sodium chromate is neutralised, and the neutral solution is electrolysed, thus producing an anode solution of sodium bichromate and a cathode solution of sodium chromate and caustic soda. The weak cathode solution is concentrated to such a strength that sodium bicarbonate is insoluble in the liquor, and the free alkali is then removed from the cathode solution as sodium bicarbonate. The treated cathode solution is mixed with a fresh portion of the neutral solution of sodium chromate, and the mixture electrolysed, thus again producing sodium bichromate, the process being continued in this way with successive cathode solutions and successive portions of the alkaline solution. — B. N.

FRENCH PATENT.

Calcareous Minerals; Process for Enriching. — E. Ledue and C. Griffiths. First Addition, dated June 9, 1904, to Fr. Pat. 339,162, Nov. 12, 1903.

VIII.—GLASS, POTTERY, AND ENAMELS.

Clay; Influence of Magnesia on. — L. E. Barringer. Trans. Amer. Ceramic Soc., 1904, 6, 86-90.

THE author, while agreeing with Maekler (this J., 1902, 914) and Hottinger (this J., 1903, 1046; 1904, 901) that magnesia is a desirable substitute for lime in porcelain bodies containing a number of active fluxes, and fired at a low heat, gives the results of some experiments showing that as the number and character of the fluxes change in the direction of porcelain bodies requiring a high firing heat, the influence of magnesia diminishes considerably. Under suitable conditions, a feldspathic porcelain body can be thoroughly vitrified, giving a non-absorbent, hard, dense product with moderate shrinkage, burning into thin-walled pieces that retain their shape well. The introduction of magnesia into a "body" of this character not only fails to give any improvement, but increases shrinkage, lowers the density, "shortens" the mixture,

and imparts to the ware a tendency to "stick" during the firing.—A. S.

Clays; Investigation of the E. G. Acheson Process of Toughening — Le Roy H. Minton. Trans. Amer. Ceramic Soc., 1904, 6, 231—259. (See U.S. Pat. 722,791 and Eng. Pat. 3630 of 1903; this J., 1903, 196 and 697.)

In the author's experiments a liquor prepared by extracting oat-straw with distilled water was used. The results obtained are given in tables and curve-diagrams. From a financial standpoint the method is restricted to the higher grades of the ceramic industry, i.e., to those classes in which the cost of the raw material is very small as compared with the value of the final product. A great improvement in strength and hardness is produced by the treatment when the clays are worked by the plastic method, but the effect is very small when the "slip" method is employed, as is customary in nearly all white-ware plants. (See also this J., 1903, 1195; 1904, 661.)

—A. S.

Faience v. Majolica. S. G. Burt. Trans. Amer. Ceramic Soc., 1904, 6, 109—113.

THE author draws attention to the need of a distinct and definite terminology. He suggests the following definitions for faience and majolica:—*Faience*: Pottery in which the coloured clay body is covered with a clear glaze. *Majolica*: Pottery in which the coloured clay body is concealed by an opaque enamel.—A. S.

Crystalline Glazes; Notes on the Production of — R. T. Stull. Trans. Amer. Ceramic Soc., 1904, 6, 186—193.

CRYSTALLINE glazes may be divided into two classes. The first class comprises the Aventurine glazes, and is produced by a mixture in which there is an excess of one or more metallic oxides; or by applying these oxides to the body or bisque before dipping it in the glaze. The second class consists of the true matt glazes, or those in which the whole mass is crystalline. Experiments made to determine the effects of different ceramic materials, showed that the strongest tendencies to crystallisation are imparted to glazes by those elements of low atomic weight, the oxides of which go to make up the RO bases, such as sodium, potassium, magnesium, calcium, manganese, ferrous iron, zinc, &c. Elements of high atomic weight, such as barium, lead, &c., when used in sufficient quantities, appear to retard crystallisation. Of the elements the oxides of which form the acid portion of a glaze, those of higher atomic weight, such as silicon, titanium, phosphorus, &c., are the best for inducing crystallisation, whilst those of lower atomic weight, such as boron, act adversely. In some cases, the introduction of an oxide of the R_2O_3 type materially assists crystallisation. The author, in preparing crystalline glazes, takes as a working basis a natural crystalline silicate or titanosilicate, and prepares experimental mixtures in which the effects of various modifications of the original mixture are shown. The best results are obtained by applying the glaze over a hard, vitrified body which has been fired at a temperature two or three cones higher than that at which the glaze matures. For colouring purposes, in most cases, 0.03 per cent. of a colouring oxide may be added without any prejudicial effect, but an addition of more than 0.05 per cent. interferes with the crystallisation. (See also this J., 1904, 606.)—A. S.

Silica Content of Glazes; Table for quickly Obtaining the —, where the Total Oxygen-Ratio and the Alumina are given. R. C. Purdy. Trans. Amer. Ceramic Soc., 1904, 6, 260—268.

By the aid of the table, which fills six pages, there can be found for any given equivalent of alumina, the corresponding equivalent of silica for any desired oxygen-ratio; and also, the oxygen-ratio of any combination of RO, Al_2O_3 and SiO_2 .—A. S.

UNITED STATES PATENTS.

Opal Glass; Process of Making Translucent — J. Kempner, Berlin. U.S. Pat. 777,734, Dec. 20, 1904.

THE translucent opal is made from a frit composed of 100 parts of felspar (poor in lime) and sodium silicofluoride, 160 to 180 parts of silicic acid (sand) and $37\frac{1}{2}$ to 50 parts of "soda."—W. C. H.

Glass-Pot Furnace. W. T. Nicholls, Wellsburg, W. Va. U.S. Pat. 779,235, Jan. 3, 1905.

A REGENERATIVE glass-pot furnace is provided with a central eye, and means for continuously feeding a fuel mixture upward through the eye, as well as a series of outer downtake-flues for the products of combustion leading through the bench, curved flues to which the downtake-flues lead, single-surface regenerators, and reversible connections between the curved flues and the regenerators. —A. G. L.

FRENCH PATENT.

Glass; Process of Rolling — without Stretching. L. A. Garchey. Fr. Pat. 339,205, Dec. 3, 1903.

THE glass is poured on to a movable table of cast-iron or other metal, on which are placed lateral ridges of the same height as the thickness of the plate to be made. The table is then moved below a rotating cylinder, which evenly distributes the glass over it. The table is then moved below a second rotating cylinder provided with cutting discs at intervals, which cut the glass longitudinally; if desired, enamel may then be poured on to the surface of the glass. The process may be modified by using a fixed table and travelling cylinders.—A. G. L.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Refractory Ceramic Products; Determination of Melting-Points of — W. C. Heraeus. Z. angew. Chem., 1905, 18, 49—53.

THE author's furnace consists of a tube of pure iridium 200 mm. long, 40 mm. diameter, and 0.2 mm. thick, strengthened at the ends by platinum rings, and furnished with appropriate connections to a source of current which can yield up to 1200 amperes at 5 volts. The tube is enclosed in an outer tube of fused magnesia, which again is surrounded by an outer fireclay cylinder of 160 mm. diameter, the space between being packed with fragments of fused magnesia. The furnace is mounted so as to be movable in any direction. Temperatures were measured by a thermo-element of iridium and iridium-ruthenium (10 per cent. of the latter metal), which was calibrated up to 1600° C. by comparison with a standard element of platinum and platinum-rhodium, and at 1780° by melting platinum; extrapolation then gave temperatures up to 2000° C. The objects to be fused were placed on an iridium plate in the centre of the tube, the ends of which were closed by perforated fireclay stoppers, through one of which passed the thermo-element, whilst through the other the process could be observed by means of a telescope about 1 metre distant. In this way the temperatures both of incipient softening and of complete fusion could be determined. Preliminary experiments showed that with pure clays having a definite melting-point, neither the rate of heating nor the size of the trial piece affected the result; and the fused mass—which

had always a porcelain-like fracture on breaking after cooling—gave the same melting-point when remelted. The melting point of a number of clays, etc. and of Seger cones, as determined by the above method, are given. An important series of measurements was made by placing the furnace vertically, and allowing the end (1 mm. square) of a weighted iridium rod to rest on the trial piece. By means of a lever and scale attached to the upper end of this rod, the rate at which it sank into the mass at different temperatures, and hence the rate at which the mass softened with rise of temperature, could be determined. Great differences were found in this respect among clays, some softening slightly far below their melting-points, and then showing little change till close to melting, whilst others became steadily softer from the temperature of incipient softening up to complete fusion. The following Table gives an indication of some of the results obtained:—

Substance.	1	2	3.	Differences	
	Melting pt.	Incipient softening.	Speed of sinking of red 1 mm. per min.	3-2	1-3
	° C.	° C.	° C.	° C.	° C.

—J. T. D.

Firebrick: Peculiar Action of Soluble Salts on —.
H. Seger and E. Cramer. *Tonind-Zeit.* 1904, 28, 1707—1708.

In a works where broken firebricks are ground and mixed in small proportions with fire-clay, the unburnt bricks were found covered with an incrustation similar to that occasionally occurring on bricks. On being burnt, however, the bricks proved to have sustained little damage, though other bricks, made from unmixed fire-clay and fired in the same kiln, were extensively corroded with bubbles and froth-like markings on the surfaces exposed to the fire-gases. Suspicion being cast on the broken firebrick, a sample was extracted with water, and the solution was found to contain soluble matter corresponding to the following calculated percentages:—Potassium sulphate, 0.04; sodium sulphate, 25.56; sodium chloride, 2.07; magnesium sulphate, 0.67; calcium sulphate, 1.45;

Sand-Lime Bricks. H. Gerlings. *J. Chem., Metall. and Mining Soc., S. Africa.* 1904, 5, 124—127.

GLASENAPP has shown that very much more silica is attacked in a given time in the case of sand-lime bricks made with steam under high pressure than when steam at atmospheric pressure is used. Thus, using coarse sand and a pressure of 147 lb., 7.58 per cent. of soluble silica was obtained after 8 hours' hardening, whilst with fine sand and ordinary pressure, only 3.06 per cent. was obtained in the same time. The fineness of the sand also plays an important part. The formula $\text{CaH}_2(\text{SiO}_3)_2$ requires only 3 per cent. of lime, but in practice from 4 to 7 or even 10 per cent. is used. When pure kaolin is substituted for the quartz, the silica is not so readily attacked, but ordinary impure clays give better results, especially if the clayey substance is washed out first.—A. G. L.

Black Speckle for use on a Red Face Brick: Note on a —.
L. E. Barringer. *Trans. Amer. Ceramic Soc.,* 1904, 6, 198—202.

Is an attempt to prepare a "red mottled" brick, i.e., a black speckle on a red body, corresponding to the buff mottled brick obtained by adding coarse pyrolusite (manganese dioxide) to No. 2 fireclays, it was found that at the temperature (cone No. 1) at which the red clay burned to a hard dense body, there was no fluxing effect on the pyrolusite. Satisfactory results were obtained, however, by using a manganese frit of the composition: 0.747 MnO_2 , 0.253 Na_2O , 0.509 SiO_2 , prepared by fusing together commercial ground pyrolusite, soda ash and flint. The best results were obtained by grinding the frit to 120-mesh, making it into a thick "slip," flecking the faces of the bricks with the "slip" by means of a brush, and burning the mottled bricks in the usual way.

—A. S.

Drying: Contribution to the Technology of — (Brick-Driers). R. H. Minton. *Trans. Amer. Ceramic Soc.,* 1904, 6, 269—286.

THE author gives details of a calculation made to show what can be done in the utilisation in brick-driers of the waste-heat from cooling kilns. The calculation is divided into the following sections:—(1) Heat consumption; (a) evaporation of water; (b) heat carried out by clay in the bricks; (c) heat carried out by the iron brick-cars; (d) radiation from exterior of drier. (2) Volume of hot air required. (3) Heat-loss, i.e., heat carried away by air. (4) Available heat.—A. S.

Clays: Note on the Tensile Strength of Raw —. H. Ries. *Trans. Amer. Ceramic Soc.,* 1904, 6, 79—82.

WITH a view to determining whether the tensile strength of air-dried clays is influenced by interlocking of the grains, the author examined five samples of clay of varying strengths. The results are shown in the following table:—

Constituents of Clay.	Percentages.				
	1.	2.	3.	4.	5.
Clay substance, 0.005—0.0001 mm. diam.	87.96	30.645	22.00	44.00	59.00
Fine silt, 0.005—0.01 mm. diam.	6.95	14.21	5.66	7.11	11.00
Silt and fine sand, 0.01—0.25 mm. diam.	3.00	5.585	26.55	24.35	14.70
Medium sand, 0.25—0.5 mm. diam.	1.00	6.400	11.45	7.80	3.50
Sand, 0.5—1 mm. diam.	—	42.95	33.44	16.35	11.40
Totals	98.91	99.79	99.10	99.61	99.60
Average tensile strength, lb. per sq. in.	20	105	289	297	453

sulphates of aluminium, manganese and iron, 0.25; and silica, 0.04 per cent.; total 30.08 per cent. of soluble matter. On heating the evaporation residue to the temperature of Seger cone 3, it was found that 8 per cent. of it volatilised within a few minutes, so that the injury was evidently produced by the volatilisation of sodium sulphate in the kiln. The broken firebrick had apparently been used in some chemical works, and there become impregnated with the sodium salt.—C. S.

They indicate that an excessive amount of clay particles weakens the strength of the clay in the same manner as a large amount of "sand." Those clays will give the best results, which contain a mixture of grains of several sizes, with the clay substance preponderating. In accordance with this theory of interlocking grains, it was found possible to prepare from two different clays a mixture having a tensile strength higher than that of either of the clays alone. The author considers that it

incorrect to use the tensile strength as a measure of the plasticity of clays.—A. S.

hydraulic Lime: Production and Application of Bagged—E. Pasquay. *Tonind. Zeit.*, 1904, 28, 1688–1689.

In burning this lime, preference should be given to right kilns, the product possessing superior hydraulic properties to that burned in "ring" kilns. The quicklime is slaked with 12–14 per cent. (volume) of water soon as drawn from the kiln, and is piled in heaps about 8 feet high for a fortnight. If the slaking period is reduced, the quality can be improved by storing for 4–6 weeks in silos. If ground and "bagged" without kiln, the expansion in damp weather will burst the bags, and the mortar made from such lime will not harden properly. After screening, the lumps are ground and mixed with the screened powder, and, indeed, these lumps greatly improve the hydraulic and binding properties of the lime. They contain, on the average, about 40 per cent. of aluminium silicate and 50 per cent. of lime. The ground lime should be again stored in silos or dry storehouses for some time before bagging. In use, the bagged lime is mixed dry with the sand, and then worked up with the necessary amount of water. Mixing is best performed a little time before the mortar is needed, the plasticity of the mortar being thereby improved. This lime is superior to that slaked in pits, inasmuch as it hardens sooner, taking only 30–36 hours to set, and there is no trouble arising from the presence of unslaked lumps. The mortar has double the tensile strength of that from unslaked lime, the preparation takes less time, and the operation of producing a uniform mortar is readily superseded. Though the first cost is somewhat higher, the author's experiments prove that the ultimate cost of the mortar is about 5 per cent. cheaper, whilst the tensile strength of the mortar from 1 part of lime and 2 of sand is about 5.06 kilos. per sq. cm., as compared with 2.20 kilos. in the case of pit-slaked lime; and with 3 parts of sand to 1 of lime the relative strengths are 3 kilos. and 1.0 kilos respectively per sq. cm.—C. S.

Blast-Furnace Slag: Granulated—H. Seger and E. Cramer. *Tonind. Zeit.*, 1904, 28, 1687.

In contrast to the general assumption among makers of "iron" Portland cement, that the blast-furnace slag is of constant composition, two samples, one white, the other yellowish, recently examined by the authors, gave the following results, the figures in brackets relating to the yellow slag:—Insoluble matter, 3.95 per cent. (1.25 per cent.); containing silica, 3.45 per cent. (0.3 per cent.); and R_2O_3 , 0.45 per cent. (0.32 per cent.). The soluble matter consisted of silica, 29.87 per cent. (35.12 per cent.); alumina, 12.72 per cent. (10.29 per cent.); iron oxide, 0.82 per cent. (0.76 per cent.); lime, 46.88 per cent. (47.25 per cent.); magnesia, 2.85 per cent. (2.83 per cent.); sulphur trioxide, trace (0.12 per cent.); sulphur, 0.4 per cent. (2.49 per cent.); loss on calcination, 1.89 per cent. (1.23 per cent.). The chief differences are in the proportions of soluble silica and of alumina, both samples being characterised by a relatively high content of sulphide of phosphorus.—C. S.

Portland Cement: Influence of Ground Ores on the Crushing Strength of—H. Seger and E. Cramer. *Tonind. Zeit.*, 1904, 28, 1662–1663.

From the results of the tests made by the authors it would seem that the practice of adding iron filings or ground ores to cement paying to diminish wear caused by traffic, is less advantageous than the use of an equal amount of ground sand. The crushing strength of a mixture of 1 part of Portland cement and 3 parts of sand was found to be average 315.7 kilos. per sq. cm. Replacing 0.25 part of the sand by ground ore raised the figures to 394.5 kilos. per sq. cm. By substituting ground sand for the ore, the strength was increased to 487.0 kilos. per sq. cm. Similarly, in abrasion tests after storing in water for a month, the ground sand mixture gave the best results, the loss in

weight being only 13 gms. as against 18 gms. in the ore mixture and 18 gms. in the sand mixture.

Cement: Notes on—A. A. B. *Amer. Ceramic Soc.*, 1904, 6, 140–141.

Limits of Free Silica and Calcium Oxide in Portland Cements manufactured by the Dry Grinding Process. Experiments were made with cement consisting of varying proportions of kaolin, pottery flint and whiting, together with so much red Clinton iron ore that the cements in all cases contained about 3 per cent. of ferric oxide. It was found that the ratios of combined to free silica and of silica to alumina are of great importance. The best results are obtained when the ratio of combined to free silica is 1:2.56, and of silica to alumina 3:1. The most satisfactory ratio of lime to silica depends largely upon the fineness of grinding, but, in general, the best results are obtained with dry-ground material having a silica to alumina ratio of 3:1, when the formula $(2.8CaO, SiO_2)(2CaO, Al_2O_3)$ is adhered to. These results were confirmed by tests made with a siliceous clay and a hard limestone occurring in Ohio (see following table).

Formula.	Tensile Strength 137–28 days.	Boiling Test
	lb. per sq. in.	
$(2.9 CaO, SiO_2)(2 CaO, Al_2O_3)$	200	Good.
$(2.8 CaO, SiO_2)(2 CaO, Al_2O_3)$	360	Good.
$(2.7 CaO, SiO_2)(2 CaO, Al_2O_3)$	190	Good, but oil glass.

Effect of Calcium Hydroxide on Natural Cements. The author examined the effect of adding 5 per cent. of dry slaked lime to four different specimens of ground natural cement, prepared by burning the natural cement rock till practically all carbon dioxide was expelled. It was found that the addition caused an increase in the tensile strength of the cement of from 44.4 to 170 per cent. Experiments with natural cement mortars, to which varying amounts of lime paste were added, gave the following results:—

Composition of Mixture.	Tensile Strength after 26 weeks; 1:2	Gain in Tensile Strength
	lb. per sq. in.	Per cent.
Natural cement	292	
96% cement + 4% lime	335	14.7
92% cement + 8% lime	325	11.4
90% cement + 10% lime	325	11.4
85% cement + 15% lime	322	10.4
80% cement + 20% lime	357	22.3
75% cement + 25% lime	304	4.1

It appears, therefore, that the addition of dried calcium hydroxide during the grinding of the natural cement gives the best results. (See also this J., 1903, 1048).—A. S.

Concrete: Impermeability of—to Water. Feret. *Tonind. Zeit.*, 1904, 28, 1578; *Chem. Zeit.*, 1905, 29, Rep. 8.

The author finds that the permeability of concrete to water varies inversely with the proportion of cement in the mixture, and the fineness of the cement particles present. Furthermore, the permeability is reduced to a minimum when the coarse and fine particles are in equal quantity, with a moderate proportion of medium particles; it is also rapidly lowered when salt or fresh water is allowed to circulate freely in the concrete. In some cases it was ascertained that the water penetrating the mass, dissolves out lime, which is reprecipitated near the surface and thus closes up the pores; and on this basis, experiments were successfully made in rendering concrete impermeable by treatment with slaked lime. Sodium silicate, soap and alum are also recommended, but the best method is to plaster the concrete with rich cement mortar.—C. S.

Fireproof Coatings. F. A. Eymer and Eymer Ges. m.b.H. Frankfurt-on-Maine, Germany. Eng. Pat. 1400, Jan. 19, 1904.

SEE Fr. Pat. 339,641 of 1904; this J., 1904, 715.—T. F. B.

Fire-proof, Acid-proof and Electrically Insulating Material; Improved ——. U. A. Marga, Dieghem, Belgium. Eng. Pat. 25,128, Nov. 18, 1904.

THE material, called "Refragor," is made by mixing ten parts of previously ignited asbestos with 1 part of litharge or lead dioxide, manganese dioxide or other oxides, and 3 parts of linseed or other oil. A paste is produced which can be moulded: this is allowed to cool, and after it has become harder through the continued oxidation of the oil, a solvent such as alcohol or ether, or a mixture of the two, is added in sufficient quantity to make the material moist enough to be worked. The mixture is then forced by pressure or rolling into a metallic cloth. The oxidation of the oil is quickened by adding cellulose to the mixture and then submitting the objects manufactured to a high temperature. To make them more acid-proof they are dipped into dilute sulphuric acid; or else the linseed oil may be heated to about "250°" and the necessary quantity of oxidising material added.—A. G. L.

Fireproof Sheet (Asbestos, &c.): Manufacture of Fibrous ——. J. B. Watson, Shorne, Eng. Pat. 25,702, Nov. 25, 1904.

THE fibro-cement, asbestos, or other pulp is supplied to a service-box, in which it is kept from setting, and which discharges it by means of a channel and apron in regulated width and depth on to a wire sheet travelling over a wire cloth drum or drums serving to drain the water from the pulp, which is squeezed between the wire drum and a felt-covered couch roll or rolls. The film formed is picked up by the felt and passed on to a collating drum; it is then wound around this drum and compressed together with the preceding layers between the drum and a roll supporting the drum so as to consolidate the successive film layers into a film sheet until the desired thickness of sheet is attained, after which the sheet produced is severed and unrolled from the drum. Adhesion between the successive layers wound on the drum may be caused by placing cementitious matter between the layers. Wire cloth may also be fed on to the drum together with the fibrous layers, and incorporated with them.

The machinery for carrying out the above operations is also claimed.—A. G. L.

Refractory Material, Products of Silica as a ——. L. Williams and H. Tomkins, Stockton-on-Tees. Eng. Pat. 4433, Feb. 23, 1904.

As a binding material for silicious bricks, blocks, ganister and the like for metallurgical purposes, in place of lime, the inventors propose some compound of magnesium; either raw magnesite (magnesium carbonate), which may be mixed with water to form a "milk," or calcined magnesite, which, with water, forms magnesium hydroxide. It is said that the binding power is equal to that of lime, 3 per cent. of raw or calcined magnesite being capable of binding 97 per cent. of silicious material containing the lightest known percentage of silica, and the magnesite having much less tendency than lime to flux the silica at high temperatures, risk of fusion is thus decreased.—W. C. H.

Kilns for Burning Bricks, Tiles and other Clay Goods, and Lime and Cement; also for Burning Sanitary Ware and for Salt Glazing. F. J. R. Lee, Cardiff. Eng. Pat. 27,834, Dec. 19, 1904.

EACH kiln of a series is connected with one or more double flues, having openings between each of the two sections, as well as shafts or connections between each of these sections and the interior of each kiln. By means of flues with controlling dampers, &c. the heat given off in any kiln may be conducted to any other, not

necessarily adjacent to it, and utilised for the drying of "green" goods.—A. G. L.

Blast Furnace Slag: Utilisation of — and Similar Materials. T. Twynam, Leeds. Eng. Pat. 4557, Feb. 24, 1904.

FINELY-GROUND slag is moistened with water and the pressed or moulded into bricks, &c. These, together with the moulds, are then stacked in a chamber kept at about 100° C., and subjected at this temperature to the action of gases containing carbon dioxide, such as exhaust gas from gas engines, until thoroughly hardened, 24 hours being usually sufficient. Solid lumps or chippings may also be mixed with the powder before moulding. It is convenient to employ a tunnel-shaped chamber, through which trucks laden with the bricks, &c., travel slowly.—A. G. L.

UNITED STATES PATENTS.

Wood; Process of Fireproofing ——. G. Blenio, New York. U.S. Pat. 779,761, Jan. 10, 1905.

THE wood is first steamed, and then, after being dried, soaked in a hot solution of ammonium phosphate and starch.—A. S.

Clay; Process of Treating ——. D. B. Williams, Connellsville, Pa., Assignor to J. R. Stauffer, Scottsdale, Pa. U.S. Pat. 779,195, Jan. 3, 1905.

CLAY is moulded and dried, and then embedded in amorphous coke within a closed chamber. The whole is then surrounded by fuel-coke, which is fired, so as to bring the confined amorphous coke to an incandescent condition in which it is maintained until the clay has hardened.—A. G. L.

Clay Product and Process therefor. D. B. Williams, Assignor to J. R. Stauffer, Scottsdale, Pa. U.S. Pat. 779,196, Jan. 3, 1905.

AN abrasive product is made by mixing untreated clay material with previously hardened, crushed abrasive material, or with "carbo clay," moulding and drying the mixture and then subjecting the dry form to the action of the gas from an incandescent body of carbon, well sealed from extraneous sources of oxygen. (See preceding patent.)—A. G. L.

Rotary Cement-Kiln. G. H. Sharp, Jonesville, Mich. U.S. Pat. 778,611, Dec. 27, 1904.

THE kiln consists of an outer casing, provided with inwardly-projecting shelving, the end of which is turned up at right angles, and means for rotating the casing. Concentric cylinders are arranged within, and secured to the outer casing, and are provided with inwardly and outwardly projecting shelving, and with retaining rings at their ends. A feed-pipe with perforations extends into the ends of the cylinders and the casing, to supply material separately to each.—W. C. H.

FRENCH PATENT.

Cement-Kiln; Rotary — Heated by Water-Gas. E. Golbbe. Fr. Pat. 346,383, Sept. 20, 1904.

THE rotary kiln is furnished with a gas-generator placed so as to receive the burnt clinker, to which carbon in regulated quantity is added from a hopper placed above the generator; this carbon is gasified by a suitable mixture of air and steam blown into the generator, the heat of the burnt clinker being utilised for this operation. The ash-pit of the generator is placed below the entry-holes for the air, and extends straight downwards so as to enable the generator to be worked without closing the ash-pit, thus rendering it possible to withdraw the cement continuously from the latter. The air blown into the generator is pre-heated by passing between the double walls of the kiln proper, and the air needed for the actual combustion, which is introduced at intervals along the kiln, is heated in the same manner. Partitions provided with openings are placed inside the kiln to assist in retaining the heat and to prevent too rapid passage of the gases through the kiln.—A. G. L.

X.—METALLURGY.

Gold Milling; Use of Electro-plated Copper Plates in the Battery in —. F. W. Cuddeh. J. Chem., Metall., and Mining Soc. of S. Africa, 1904, 5, 92—95.

THE author approves the use of a copper plate within the mortar, mercury being fed in at intervals, and of several rows of electro-silver-plated copper plates outside, two ounces of silver per sq. ft. being recommended. At the Homestake Mine in June, 1902, of the total amalgam obtained, 35 per cent. was caught in the mortar box, 30 per cent. on the first row of plates, 13 per cent. on the second row, 7 per cent. on the third row, and 6 per cent. on the fourth row; the gold obtained from the amalgam from the mortar box was 820 fine, that from the first row 410, second row 556, third row 550, fourth row 495. In the 200-stamp mill there are in all 160 plates, the total amalgamated surface of which is 8640 sq. ft. The ore treated contained roughly 6 per cent. of pyrites, and 55 per cent. of silica, the remainder being hornblende and argilliferous schist or slate. The ore is very finely crushed, so that 78 per cent. passes a 10,000 mesh screen.

In the discussion, which followed the reading of the paper, most of the speakers agreed with the author that in crushing and large amalgamating areas were to be recommended, especially now that the effective cyaniding of slimes was possible, also that it was advantageous to use shaking plates. One speaker thought that when the mill water was acid, amalgamated copper plates were better than electro-silvered plates.—J. H. C.

Gold Bullion; Notes on —. A. C. Claudet. Inst. of Mining and Metall., Bull. No. 4, Jan. 12, 1905.

VITH reference to the author's previous note (this J., 1904, 1149), details of the cost of "toughening" gold bullion in England are given as follows:—

Coarse bullion treated	2830 oz. troy.
Saltpetre used, 33lb. at 2d. per lb.	66d.
Gas coke used, 112 lb. at 36s. per ton ..	22d.
One man, 8 hours at 1s. per hour	96d.
One crucible (Creusot de Paris, No. 21) ..	24d.

Total cost on 2830 oz. of coarse bullion = 208d. = 17s. 4d.

	Gold.	Silver.
Fineness of bullion—		
Before treatment	581 ..	116 per 1000
After	756 ..	136 .. 100

Thus if colonial costs were double those obtaining in England, the cost of toughening would be about $\frac{1}{4}$ per cent. of fine gold. The slags are re-melted when 10,000 ozs. have been accumulated; any gold present is in the form of pellets, and there is no real loss throughout the process. —A. S.

Chromium; New Method of Preparing Metallic —. C. Goldschmidt. Chem.-Zeit., 1905, 29, 56.

METALLIC chromium can be separated from solutions of its salts by contact with metallic zinc or its alloys. Thus if a solution of chromium nitrate be allowed to stand in the cold in a zinc vessel, chromium is deposited partly in the amorphous and partly in the crystalline form, in the course of a day. The chromium hydroxide simultaneously deposited can be removed by treatment with alkali in excess. The best results are obtained with crystalline chromium nitrate, other chromium salts not being so suitable for the purpose.—C. A. M.

Cobalt and Nickel; Alloys of —. W. Guertler and G. Tammann. Z. anorg. Chem., 1904, 42, 353—361.

THE authors determined the melting-point curves of cobalt-nickel alloys, and also the temperatures at which such alloys are transformed from the magnetisable into the non-magnetisable condition. The results are shown in the curve diagram (see figure). In this diagram the melting-point curve separates the field corresponding to the molten metal from that corresponding to the non-magnetisable crystals, and the transformation-curve divides the field of the non-magnetisable from that of the magnetisable crystals. At all temperatures between the melting-point

of pure nickel, 1481° C., and that of cobalt, 1528° C., the fused alloy is in equilibrium with mixed crystal of approximately the same composition. At temperatures on the

transformation, curve the magnetisable mixed crystals are in equilibrium with the non-magnetisable crystals. —A. S.

Zinc-Antimony Alloys. K. Mönkenmeyer. Z. anorg. Chem., 1905, 43, 182—196.

THE author determined the melting-point curve of zinc-antimony alloys, and also the time occupied from the beginning to the end of the eutectic crystallisations and polymorphous transformations. The melting-point curve has two maxima, C and E (see table), and three eutectic points, B, D and F. The composition of the alloys corresponding to these points is given in the following table:—

	[Composition in Parts per cent. by weight.	Constituents.	Melting Point.
			° C.
A	100% Zn	Zn	419
B	97.5% Zn + 2.5% Sb	Zn + Zn ₃ Sb ₂	411
C	44.96% Zn + 55.04% Sb	Zn ₃ Sb ₂	561
D	37.5% Zn + 62.5% Sb	Zn ₃ Sb ₂ + ZnSb	539
E	35.48% Zn + 64.52% Sb	ZnSb	644
F	21% Zn + 79% Sb	ZnSb + Sb	607
G	100% Sb	Sb	631

The micro-structure of the alloys was in agreement with the existence of the two compounds Zn₃Sb₂ and ZnSb. —A. S.

Metals; Microscopic Examination of —. J. H. B. Jenkins and D. G. Kiddick. Analyst, 1905, 30, 2—13.

THE paper deals mainly with the preparation, mounting and microscopic examination of sections of mild steel. It is accompanied by 10 plates, containing 41 microphotographs.—A. S.

Gold Assaying; Note on the Influence of Fine-crushing on the Assay Value. A. Whitby. XXIII., page 153.

Manganese Sulphide; Determination of — in Manganese Ores containing Barium. L. Blum. XXIII., page 153.

FRENCH PATENTS.

Steel; Manufacture of —. C. Cammell and Co., Ltd., J. E. Fletcher and W. B. Hamilton, Sheffield. Eng. Pat. 25,491, Dec. 28, 1903.

THE iron is melted in an open-hearth furnace, partly by the waste heat from a connected converter, and partly by

the combustion of gas led into the furnace together with air, which may be heated by regenerative chambers through which the final waste gases are passed on their way to the chimney. The open-hearth furnace, as shown, is mounted for tilting, so that its charge, when molten, may be run into the converter, the position of which can also be adjusted. —E. S.

Steel; Tempering and Hardening — J. T. H. Gannon, Rochdale, and W. H. Phillips, Oldham. Eng. Pat. 28,736, Dec. 31, 1903.

STEEL, Heated to from 921° F. to 1200° F., is plunged into a bath consisting of a solution of about 9 parts of nickel sulphate to 100 parts of sulphuric acid, or other suitable nickel salt in 100 parts of boiling water. —E. S.

Metals; Kyles, applicable for Treating Metals used in the Production of Basic Linings for Converters and Furnaces, and for Other Purposes. — J. W. Mackenzie, London. Eng. Pat. 28,692, Dec. 29, 1903.

THE apparatus described is designed to secure continuous or practically continuous working. A hearth-plate forms the bottom of the kiln. The cupola or kiln is supported by means of brackets on its exterior, which rest upon girders, and a clear opening is left all round between the hearth-plate and the wall of the cupola for the required height. The lower part of the cupola, in the case of a blast being used, and also the hearth-plate, are enclosed within a chamber which excludes the outer air. A hopper-shaped pusher-bar is caused to travel hoe-wise, and continuously but slowly, to-and-fro along the plate, pushing the material off the plate first on one side and then on the other, and allowing the material above to descend. The material pushed off falls on an inclined plate and thence on a continuous conveyor, by which it is conveyed to a hopper forming part of the enclosed chamber, or, in the case of a kiln into which a blast is not blown, into any convenient place. The bottom of the hopper is fitted with a door which is opened from time to time to discharge a large quantity of material in an extremely short time, during which the blast may be shut off without substantially affecting the working of the kiln, although it will probably be found unnecessary to shut off the blast during this short time. The air may be forced into the chamber and pass from thence through openings immediately above the hearth instead of through tuyeres. —A. G. L.

Blast Furnace Slag and similar Materials; Utilisation of — T. Twynam. Eng. Pat. 4557, Feb. 24, 1904. IX., page 136.

Air; Appliances for Extracting Moisture from — and *Feeding such Air to Blast or other Furnaces or Converters, or for other Purposes*. — J. Gayley, New York. Eng. Pat. 13,802, June 20, 1904.

SEE Fr. Pat. 314,399 of 1904; this J., 1904, 1095. —T. F. B.

UNITED STATES PATENTS.

Tool-Steel; Manufacture of — J. A. Matthews, Syracuse, N.Y., Assignor to Crucible Steel Co. of America, N.J. U.S. Pat. 779,171, Jan. 3, 1905.

THE claim is for high-speed steel containing less than 1 per cent. of carbon, more than 6 per cent. of molybdenum, and from 0.10 to 1 per cent. of vanadium. —J. H. C.

Smelting Ore; Method of — J. Gayley, New York. U.S. Pat. 779,037, Jan. 3, 1905.

THE blast employed is thoroughly dried, whereby the amount of fuel required is materially lessened. —J. H. C.

Smelting Furnace. — A. E. Manchester, Newburgh, N.Y. U.S. Pat. 779,953, Jan. 10, 1905.

THE furnace is attached to a forehearth by an interposed cut-off valve, comprising two longitudinal members, having an open portion and a closed portion, and means being provided for securing the open portion or the closed portion of each member to its respective furnace or forehearth, as well as for securing the two together. —E. S.

Furnace [for Roasting Ores]; Rotary — H. C. Davey, San José, Cal. U.S. Pat. 779,119, Jan. 3, 1905.

THE furnace consists of a series of inclined revolving cylinders each having a conical receiving end forming substantially a close joint with the masonry in which it turns; an enlarged head rigid with the discharge end of the revolving cylinder and provided with an outwardly extending annular flange; a stationary head abutting on the head of the cylinder and having an annular channelled interior at one end to receive the said flange and a delivery shoot; a furnace near to the stationary head which delivers the products of combustion thereinto and into the cylinder; an open receiver in communication with the delivery shoot of the stationary head and with the conical inlet of the succeeding cylinder, all in combination as described. Thrust-bearings, consisting of annular bevelled rings on the cylinder and corresponding bevelled pinions journaled at right angles with the cylinder axis, are provided to maintain the joint between the conical inlet and the masonry. —J. H. C.

Or. Briquette; Furnace for Burning — G. Gröndal, Djursholm, Sweden. U.S. Pat. 780,337, Jan. 17, 1905.

SEE Eng. Pat. 23,764 of 1903; this J., 1904, 118. —T. F. B.

Metallic Compounds; Recovering — from Solutions. — S. W. Vaughn, Lorain, Ohio, and J. W. Cabot, Johnstown, Pa. U.S. Pat. 779,058, Jan. 3, 1905.

THE metals are treated with a solution of an "iron cyanide of an alkali," whereby they are precipitated as "iron cyanides," which by subsequent treatment with caustic alkali are converted into oxyhydrates, alkali iron cyanides being at the same time reformed for subsequent use. Any excess of precipitant left in the original solution is separated by means of a soluble zinc salt. —J. H. C.

Metal Values [Copper]; Recovering — from Slag and Mine-Waters. — R. Baggaley, Pittsburg, Pa. U.S. Pat. 779,252, Jan. 3, 1905.

WATERS containing copper are made to drop through successive vessels containing iron or comminuted smelter slag. —J. H. C.

Metals [Iron and Zinc]; Obtaining — from their Ores. — S. Peacock, Chicago, Ill. U.S. Pat. 779,310, Jan. 3, 1905.

ORES containing iron and zinc are pulverised and then roasted at such a temperature as will reduce the iron but not the zinc. The mass is cooled in a reducing atmosphere, the iron separated out, and the zinc is subsequently reduced in the usual manner. —J. H. C.

Zinc or other Sulphides; Apparatus for Recovering — from their Ores. — J. H. Gillies, Melbourne. U.S. Pat. 780,281, Jan. 17, 1905.

SEE Eng. Pat. 20,159 of 1904; this J., 1904, 1150. —T. F. B.

Mineral Work; Manufacture of — T. B. Parkison, Muncie, Ind. U.S. Pat. 779,397, Jan. 3, 1905.

THE molten slag is projected through smoke and steam. —J. H. C.

FRENCH PATENT.

Metals; Apparatus for Determining the Temperature of Heated and Fused — Soc. Schneider et Cie. Fr. Pat. 339,206, Dec. 4, 1903.

THE method is based on the fact that metals when heated acquire different tints at definite temperatures. It consists in comparing the tint of the heated or fused metal with that of one of a series of coloured transparent discs (e.g., wafer-shaped coloured pieces of glass). The apparatus, in one of its forms, is a telescopic tube having at one end an incandescent lamp, and at the other end an eye-piece for observation, whilst midway between the ends provision is made for the insertion of a frame (circular, or a long strip) carrying at regular distances the series of coloured discs, adjustments being provided whereby any one of the discs may be brought into the field. —E. S.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(A).—ELECTRO-CHEMISTRY.

Alternating Current; Electrolysis with —. C. Rossi. *L'Ind. Chimica*, 1904, 6, 333–335. *Chem. Centr.*, 1905, 1, 61.

THE reactions which take place when potassium chlorate solutions rendered faintly acid with sulphuric acid are electrolysed between copper electrodes with alternating current, are very complicated. The copper electrodes become coated with cuprous chloride; the solution contains chlorine and copper. Bluish-green basic copper chlorate, $\text{Cu}(\text{ClO}_3)_2 \cdot 3\text{Cu}(\text{OH})_2$, separates from the solution at the electrodes and on the bottom of the containing vessel. With direct current, cuprous chloride is formed at the anode, together with some basic chlorate and chloride, whilst a mixture of cupric hydroxide, copper, cupric oxide and cupric chloride separates from the electrolyte; the solution contains no copper, but only potassium chlorate and chloride. The copper goes into solution in the form of cuprous ions, reduces the chlorate, and is precipitated by the potassium hydroxide formed at the cathode. Similar results are produced with iron electrodes.—A. S.

Cadmium Amalgam Lamp of Quartz. O. Lummer and E. Gehrecke. *Z. Instrumentenkunde*, 1904, 24, 298. *Chem. News*, 1905, 91, 27–28.

THE vacuum arc lamp filled with cadmium amalgam described by Gumlich in 1897 (*Z. Instrumentenkunde*, 97, 17, 161) was, for many purposes, superior to the mercury lamp, but it was never a real success on account of its short life. By using fused quartz, the authors have succeeded, however, in constructing a cadmium amalgam lamp capable of continued use. The lamp is of the form (compare this J., 1904, 246), and is filled with an amalgam containing 14 grms. of cadmium per 100 grms. of mercury. After being used for some time, it showed signs of deterioration, but when re-exhausted, and then again started, it acted as well as at first.—A. S.

Antimony and Tin: Electrolytic Determination and Separation of — from Solutions of their Sulpho-salts, together with a Study of the Determination of Antimony by the Trisulphide Method. A. Fischer. XXIII., page 153.

Fire-proof, Acid-proof and Electrically Insulating Material; Improved —. U. A. Marga. Eng. Pat. 25,128, Nov. 18, 1904. IX., page 136.

UNITED STATES PATENT.

Battery; Galvanic —. C. J. Reed, Philadelphia, Pa., Assignor to Security Investment Co., Pennsylvania. U.S. Pat. 778,893, Jan. 3, 1905.

THE invention comprises a receptacle containing a solution of one or more ferrous salts, such as the sulphate, and an iron electrode in the solution, and a solution of one or more ferric salts, such as the sulphate, with an inert negative carbon electrode in the solution. The two liquids are separated by a partition having a high degree of porosity for preventing rapid mixing of the two solutions.—B. N.

Spongy Lead for Secondary Battery Electrodes; Process of Making —. C. J. Reed, Philadelphia, Pa., Assignor to Security Investment Co., Pennsylvania. U.S. Pat. 778,894, Jan. 3, 1905.

ONE or more compounds of lead, such as the oxides, are mixed with finely-divided zinc or zinc dust in chemically equivalent proportions, and the mixture is subjected to the action of a liquid, such as zinc chloride, so as to form metallic lead and a soluble zinc salt, which is then washed out. The mixture, before treatment, may be applied as a coating to a lead plate, or as a filling in openings in a lead plate or frame, and may be previously mixed with an inert soluble granular material, which is washed out with the zinc salt.—B. N.

Storage-Battery Plates; Protective Covering for —. A. Meygret, Paris. U.S. Pat. 779,553, Jan. 10, 1905.

THE battery-plate consists of a retaining base, or metal body, with active material applied to it. The plate is dipped into a solution of soluble material so as to form a soluble film on the exterior face of the active material, and the plate and film are then dipped into a solution furnishing a protective coating, so that the soluble film is interposed between the active material and the covering.—B. N.

Electrode. E. F. Price, Assignor to Union Carbide Co., Niagara Falls. U.S. Pat., 779,733, Jan. 10, 1905.

THE electrode consists of calcium carbide and a carbon binder containing coked bituminous coal and a liquid hydrocarbon.—B. N.

Electrolysis [Apparatus for] —. G. Rambaldini, Miniera di Boeccheggiano, Italy. U.S. Pat. 779,735, Jan. 10, 1905.

(B).—ELECTRO-METALLURGY.

Iron and Steel Manufacture; Electric Processes for —. Electrochem. Ind. Harbord and Haandel, 1904. 179–486.

AN abstract of portions of the Report of the Canadian Commission appointed to investigate electric processes in use in Europe for iron and steel manufacture. Mr. Harbord was appointed Chemist to the Commission, and his conclusions are:—1. Steel equal to the best

Sheffield crucible steel can be produced at considerably less cost by the Kjelin, Heroult, or Keller process. 2. Electric furnaces can only produce commercially high-class steels for special purposes, and cannot compete with the Siemens or Bessemer processes for producing structural steel. 3. In the electric smelting furnaces, the reactions involved in the reduction of iron and its combination with silicon, sulphur, phosphorus and manganese, are similar to those in the blast-furnace. Any grade of white or grey iron can be produced by altering the burden and regulating the temperature; and these changes can be effected much more rapidly than in the blast-furnace. 4. Grey pig iron suitable for the acid Bessemer or Siemens process, can be produced in the electric furnace. 5. Pig iron low in silicon and sulphur, for the basic Bessemer or Siemens process, can be produced if the ore mixture contain oxide of manganese, and a basic slag is maintained by suitable additions of lime. 6. Pig iron can be produced at a cost to compete with the blast-furnace only where electric energy is cheap and fuel dear. With electric energy at £2 per E.H.P. year, and coke at 28s. per ton, the cost of production either way is about the same. 7. Where blast-furnaces are established, electric smelting cannot compete, but where ample water-power is available and coke not readily obtainable, it may be commercially successful.

Haanel augurs a hopeful future for electric smelting, when it has been developed, on a basis of further practical experiment in specially and adequately designed furnaces. In many places electric energy will be available at much lower cost than 40s. per E.H.P. year, and if it be combined with the use of peat-coke or briquetted charcoal made from mill refuse, the cost of these may be reduced to half of that taken as a basis in the report. The temperature attainable in the electric furnace being so high and so easily regulated, the process may probably be applied with advantage to the smelting of other ores besides those of iron, especially those which have hitherto proved refractory.—J. T. D.

Iron: New Method for the Preparation of Electrolytic — S. Maximowitsch. Z. Elektrochem., 1905, 11, 52–53.

ELECTRO-DEPOSITED iron is usually very hard, but exceedingly brittle, which property is ascribed to the occluded hydrogen. The author finds that using an electrolyte containing ferrous bicarbonate in which the concentration of hydrogen ions is very low, a much softer and more satisfactory deposit can be obtained. The bath is prepared by adding sodium bicarbonate, at intervals, to the solution of ferrous and magnesium sulphates. The iron only attains its best condition after the bath has been in use for several weeks.—R. S. H.

Tantalum: Its Preparation and Properties. W. von Bolton. Z. Elektrochem., 1905, 11, 45–51.

VANADIUM, niobium and tantalum have been prepared by passing an electric current through rods of some coloured oxide of these metals (in the last two cases the tetroxide) when supported in a vacuum, which is maintained in order to pump off the oxygen set free at a high temperature. By this method, coherent rods of the metal are obtained. Tantalum is also prepared in larger masses by the method of Berzelius and Rose (action of alkali metals on the alkali-tantalum fluorides), and subsequent fusion of the metal powders thus obtained with the electric arc. The melting point of the metal lies between 2250 and 2300 C.; it is very ductile, and can be drawn to wire of 0.03 mm. diam., but possesses the remarkable property of becoming extremely hard after hammering. So hard is the metal, that it is practically impossible to bore it even with a diamond point, and it is hoped to employ it for machine tools. In chemical properties tantalum approaches the noble metals. It is intended to make use of tantalum in the form of wire for the filaments of incandescent electric lamps. Such lamps only absorb about 1.5 watts per candle, as against the 3.5 watts of the carbon filament; 65 cm. of the 0.05 mm. wire are required for a 110-volt lamp. The efficient life of these lamps is 400–600 hours.

—R. S. H.

ENGLISH PATENTS.

Cells [for Production of Metallic Sodium]; Electrolytic — J. Raschen, G. C. Clayton and the United Alkali Co., Ltd., Liverpool. Eng. Pat. 215 Jan. 28, 1904.

THE sodium-lead alloy, acting as the anode, enters at the denuded lead leaving at a2, k showing the level of the alloy in the circular iron well A. The iron cover of the cell consists of outer and inner circular walls c2 and c3, a connecting conical crown c4, and a lip c dipping into the recess b surrounding the cell A. A thermomenter may be introduced at c5. The molten caustic soda forming the electrolyte is contained within the closed annular space e and fills the recess b and the space j to the level l. The hollow cathode D, preferably of nickel, is bolted to nickel radiating pole-pieces H, which dip into the electrolyte. An annular diaphragm G, of iron or nickel is suspended from the top of the cathode, so that the wall c3, the cathode D, and the diaphragm form two annular spaces e and e' which are closed hermetically at the top. Any gas formed in the cell is conveyed away through a pipe attached to c6. Sodium collects in e to the level m, and overflows through the openings d2 into f, and deposits at the bottom d3 of the hollow cathode. Air is thus prevented from coming into contact with the metal while the latter is in contact with the electrolyte, and the metal may be removed without admitting air to the cell.—B. N.

Metals: Methods of Obtaining — from Compounds containing Silicon [e.g., Aluminium from Clay]. H. A. Lewis, London. From the General Electric Co. Schenectady, N.Y. Eng. Pat. 3998, Feb. 17, 1904.

CLAY and similar substances, containing aluminium (or similar metals) associated with silicon and other impurities are heated, together with carbon, in an electric furnace such as is used in producing carborundum. The product consisting of a mixture of the carbides of silicon and aluminium, is treated with a reagent, such as caustic soda solution, whereby the aluminium carbide (and an alumina present) dissolve, with production of sodium aluminate and of methane gas, whilst the silicon carbide remains undissolved. If, however, the mixture of clay and carbon is heated to the temperature of the calcium carbide furnace, at which temperature silicon volatilises as well as iron and other impurities, then the carbides of aluminium, calcium, &c., are formed, of which only the former is soluble in an alkaline solution. From the solution of alkali aluminate, aluminium hydroxide, and from that the metal, may be obtained.—E. S.

Nickel Ores: Process for Melting — in an Electric Furnace and an Improved Crucible therefor. Société Electro-Metallurgique Française, Fives, France. Eng. Pat. 23,380, Oct. 29, 1904. Under Internat. Conv. Oct. 30, 1903.

SEE FR. Pat. 336,376 of 1903; this J., 1904, 378.—T. F. B.

UNITED STATES PATENTS.

Furnace; Electric — [for Treating Iron Ore]. D. R. F. Galbraith, Assignor to W. Stewart, Auckland, New Zealand. U.S. Pat. 779,844, Jan. 10, 1905.

SEE FR. Pat. 336,726 and 336,727 of 1903; this J., 1904, 378.—T. F. B.

Lead Ores; [Electric] Process of Reducing — P. G. Salom, Philadelphia. U.S. Pat. 778,901, Jan. 3, 1905. — The finely ground ore is spread upon the surface of a suitable cathode in the presence of a suitable electrolyte and anode, and the resulting mass of spongy lead is removed as fast as it is formed. — J. H. C.

Lead; Process of Electrolytically Refining — A. G. Betts, Lonsburg, N.Y. U.S. Pat. Re-issue 12,301, Jan. 3, 1905.

LEAD is deposited electrolytically from a solution containing an acid, such as hydrofluosilicic acid, which is strongly dissociating, and which has of itself no oxidizing or reducing action on the electrodes. The electrolyte also contains soluble lead thiosulfate, and an agent, such as gelatin, or a reducing agent, capable of restraining the crystallization of the electro-deposited lead. (See also U.S. Pat. Re-issue 12,117, this J., 1903, 805.) — B. N.

Metals; Electrochemical Separation of — W. M. Johnson, Hartford, Conn. U.S. Pat. 789,191, Jan. 17, 1905.

CLAIM is made for an electrolytic process of refining iron, in which a current is passed between electrodes of the impure iron and of substantially pure iron, immersed in a solution of ferrous ammonium chloride rendered slightly acid with an organic acid such as acetic acid. The sludge produced is removed when necessary and refined in any suitable manner. From time to time the electrolyte is subjected to a "cementation" process with scrap iron, to remove other elements and keep the iron in the ferrous condition. Claim is also made for the separation of an alloy of iron, copper and precious metals by a similar process, the precious metals being recovered from the sludge, and the copper precipitated on the scrap iron during the "cementation" process. — A. S.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

Waxes; Analysis of — G. Buchner. XXI:4. page 154.

ENGLISH PATENTS.

Soap, Washing Compounds, and the like; Manufacture of — P. C. D. Castle, Bebington, Chester. Eng. Pat. 4415, Feb. 22, 1904.

GUM tragacanth is added to soap or soap lyes with or without the addition of other substances such as glycerin, carboic acid, borax or boric acid, special claim being made for the last two. The gum tragacanth is said to increase the detergent properties of the soap, and to prevent it wasting so rapidly as ordinary soap in water. — C. A. M.

Glycerin from Spent Soap Lye; Processes for the Recovery of — and *Apparatus therefor*. W. E. Garrigues, New York. Eng. Pat. 24,100, Nov. 8, 1904.

SEE U.S. Pats. 774,171 and 774,172 of 1904: this J., 1904, 1153. — T. F. B.

UNITED STATES PATENTS.

Fatty Acids; Process of Producing — O. Liebreich, Berlin. U.S. Pat. 778,980, Jan. 3, 1905.

ACIDYL derivatives of aromatic bases (Ger. Pat. 136,917 of 1900; this J., 1903, 149; U.S. Pats. 746,638 and 748,511 of 1903; this J., 1904, 121, 195) are heated with sulphuric acid, and the sulphonated aromatic derivatives separated from the fatty acids. Or, glycerides of fatty acids (fats or oils) are treated with aromatic bases, the acidyl derivatives and glycerin separated, and the former heated with sulphuric acid as above described. — C. A. M.

Extraction of Soluble Material [Oil from Seeds, &c.]; Apparatus for Continuous — E. Bataille, Paris. U.S. Pat. 779,022, Jan. 3, 1905.

SEE Fr. Pat. 319,204 of 1902; this J., 1902, 1460. — T. F. B.

Wool-wash Waters; Apparatus for Treating the same [Fat from] — G. E. Behnen, London, Conn., and G. Taylor, New York. U.S. Pat. 789,175, Jan. 17, 1905.

THE apparatus comprises a filter press, in which the matter is removed from the wash water, and a pump, as a solvent under pressure, through the press, and into the solution of the fatty matter in a solvent, a three-valved pipe leading from the storage tank to a condenser, and receptacles for the recovered fatty matter and solvent. — T. F. B.

Wax Emulsion, and Process of Producing same. H. H. Church, Bellows Falls, Vt., Assignor to Casco Co. of America, New Jersey. U.S. Pat. 779,527, Jan. 10, 1905.

FIFTY parts of paraffin wax and 50 parts of stearic acid are melted in water by the aid of heat, a solution of 20 parts of borax is added, and the mixture is boiled for half an hour or more, with continual agitation, until frothing has ceased. (See also U.S. Pat. 778,115 of 1904; this J., 1905, 97.) — A. S.

FRENCH PATENTS.

Fatty Substances which are Hard at the Ordinary Temperature; Process for Rendering Plastic — F. Lamon. Fr. Pat. 346,197, Aug. 13, 1904.

SEE Eng. Pat. 17,866 of 1904; this J., 1904, 1102. — T. F. B.

Fats; Enzymic Decomposition of — in a Neutral Medium. E. Lombard. Fr. Pat. 346,115, Sept. 24, 1904.

A SMALL proportion of an ester of low molecular weight is mixed with the fat. Thus an emulsion of an oil with one part in 10,000 of ethyl acetate is stated to be decomposed as completely on treatment with crushed castor seeds and pure water, as when acidified water is used under the same conditions with the oil alone.

— C. A. M.

Detergents; Automatic Saponifying Autoclave for the Manufacture of Solid and Alkaline — C. Jourdan. Fr. Pat. 339,154, Nov. 7, 1902.

THIS apparatus is shown in Fig. 1 in vertical section. The alkaline lye (sodium carbonate solution of 35 B.

with about 10 per cent. of sodium silicate leaves the reservoir tank by the pipe 4, and is pumped by means of the pump 5, through the pipe 6 into the measuring cylinder 7, whence the excess above the predetermined level falls back into the reservoir through the pipe 8 controlled by a float. The measured quantity of lye passes through the coil 3 contained in the tank of water 2, and thus through the pipe 15 into one of the twin chambers 17, where the temperature is brought to about 80° C. by means of a steam coil at 110° C. At the same time the fatty matter coming from the tank through the pipe 10 is pumped by means of the pump 11 into the reservoir chamber 12, which has a double bottom, the excess being returned to the general tank through the pipe 13. A steam tube 14 passes through the pipe 10, with the object of keeping the fat liquid whatever the external temperature may be. The regulated amount of fat passes through the pipe 14, the cock of which is opened and closed by an endless chain into the second of the twin chambers 18, where it is heated to about 45° C. by means of a steam coil. The supply of steam to the twin chambers is regulated by the cocks 24 and 25. As soon as the required temperatures are obtained the cock 27 is opened, and the lye falls into the saponifying chamber 28. This contains a horizontal shaft on which revolve paddles 37 and 38 (Fig. 2) and an Archimedean screw 39, whilst horizontal motion is

imparted to the helical stirrers, 34 and 35, by means of the wheels 32 and 33. The chamber is also fitted with a perforated partition, 39, supported by iron ends rivetted to the interior of the chamber. When the whole of the lye has entered the saponifying chamber, the cock 41 is opened and the fat admitted, the pressure driving it through the perforations of the partition 39, so that it falls into the lye in a finely divided state and is thoroughly mixed by means of the paddles, &c. Steam is not admitted to the autoclave until the whole of the fat has been introduced, this being indicated on the pressure gauge 42. The saponified mass is transferred through the pipe 43 to the vessel 45 a certain proportion of sodium carbonate (5 to 20 per cent.) being simultaneously added, and after thorough admixture, is discharged through the outlet controlled by the handle 46. It is stated that the entire operation can be carried out within 15 minutes.—C. A. M.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

(A.)—PIGMENTS, PAINTS.

ENGLISH PATENTS.

Zinc Blends and other Substances Containing Zinc; Treating — W. Simm, H. Simm, R. Storey, and J. S. Sellers. Eng. Pat. 4058, Feb. 18, 1904. XI A., page 139.

Sulphide of Zinc; Process for the Manufacture of — E. Marlier, Brussels. Eng. Pat. 4295, Feb. 20, 1904. See Fr. Pat. 338,959 of 1903; this J., 1904, 545.—T. F. B.

Paint; Antifouling and Preservative — for Ships' Bottoms and other Submerged Structures. G. G. Schobert, Birmingham. Eng. Pat. 24,989, Nov. 17, 1904.

A PAINT for protecting materials against corrosion and against growths of animal or vegetable matter, consist of calcium arsenite ground to a paste with linseed oil and incorporated with resin, asphalt, and zinc oxide or other pigment.—T. F. B.

UNITED STATES PATENTS.

Lampblack; Process of Making —, from Acetylene. J. M. Morehead, Chicago. Assignor to Union Carbide Co., Niagara Falls, N.Y. U.S. Pat. 779,728, Jan. 10, 1905.

A GASEOUS mixture of acetylene and oxygen or air, the proportion of air being above 1 per cent., and preferably about 4.5 per cent., is made, then compressed and passed into a vacuum explosion vessel. The mixture is exploded, the minimum pressure required to effect dissociation being used, namely, about 60 lb. per square inch. The resulting carbon is removed from the explosion vessel by an air-blast.—B. N.

Paint, and Process of Producing same. W. A. Hall, Bellows Falls, Vt., Assignor to Casein Co. of America, New Jersey. U.S. Pat. 780,001, Jan. 10, 1905.

A LIQUID paint or enamelling composition is prepared by adding 10 parts of asbestos to 90 parts of sodium silicate, agitating the mixture to reduce the asbestos to a finely-divided condition, and finally incorporating with the mass, 200 parts of an earthy or mineral base, such as talc or whiting, 15 parts of a vegetable oil, and 100 parts of water.—A. S.

Paint; Oil — M. Hérisson, Paris. U.S. Pat. 780,340, Jan. 17, 1905.

SEE Fr. Pat. 342,550 of 1904; this J., 1904, 989.—T. F. B.

FRENCH PATENT.

Paint; New Base for —, and the Method of Manufacturing it. L. B. Germain. Fr. Pat. 339,180, Nov. 21, 1903.

THIS new base for use in paint manufacture is prepared by mixing together in suitable proportions zinc sulphide (20 to 25 parts by weight), zinc oxide (15 to 20) and barium silicate (40 to 55). The barium silicate may be replaced by silicates of aluminium, magnesium, zinc or lead.—M. C. L.

(B.)—RESINS, VARNISHES.

Sealing-Wax and Copal Resin; Preparation of — C. Goldschmidt. Chem.-Zeit., 1905, 29, 33.

THE author recommends the use of formaldehyde-resins for the preparation of sealing-wax. For a blue wax, the resin obtained by heating a mixture of formaldehyde, hydrochloric acid and methyldiphenylamine for two hours, and oxidising the reaction-product, is most suitable. The formaldehyde-resins are cheap, non-poisonous, and stable, and appear to be very suitable for the preparation of a substitute for copal resin.—A. S.

Boiled Linseed Oils; Rules for Testing —, issued by the Russian Ministry of Marine. XXIII., page 155.

FRENCH PATENT.

Varnish Containing Wood Extract. M. Flandrak. Fr. Pat. 346,164, Sept. 10, 1904.

A WOOD or bark extract, in the crude state, or partially freed from tannin, is dissolved in alcohol, ether, or other solvent, and applied as a varnish to wood. This varnish

covered with a coating of a lac varnish to give a brilliant finish.—T. F. B.

(C.)—INDIA-RUBBER, &c.

Rubber of Landolphia Pterisanum from the East Africa Protectorate. Bull. of the Imperial Inst. (Suppl. to the Board of Trade J.), 1905, 2, 221—222.

SAMPLE of rubber from the East Africa Protectorate, stated to have been prepared from *Landolphia pterisanum*, is very porous, and contained a considerable quantity of acid liquor; it was soft and rather spongy, but was satisfactory as regards elasticity and tenacity. On analysis it was found to contain moisture, 17.8 per cent.; outchouc, 67.7 per cent.; resin, 11.1 per cent.; dirt, 4 per cent.; and ash (included in dirt), 1.2 per cent. The percentage of caoutchouc (82.5 per cent. on the dry sample) is satisfactory, but the resin content is high, compared with that of *Landolphia Kirkii* obtained from the same district. The rubber is valued at about 3s. per lb. in London, but a carefully prepared sample would probably be worth considerably more.—T. F. B.

FRENCH PATENT.

Rubber; Process for Manufacturing a Substitute for —. H. Tichsen. Fr. Pat. 346,369, Sept. 20, 1904. Eng. Pat. 17,579 of 1904; this J., 1904, 1154.—T. F. B.

XIV.—TANNING, LEATHER, GLUE, SIZE.

Melottanic Acid; Decomposition of —. Utz. Chem.-Zeit., 1905, 29, 31—32.

SOLUTION of 5 grms. of tannin in 100 c.c. of water was treated with 8 c.c. of a 25 per cent. solution of hydrochloric acid and boiled under a reflux condenser. It was found that after one hour, enough sugar had been produced to give the Bandouin reaction (rose coloration on heating with hydrochloric acid and sesame oil). After long continued boiling, the liquid was repeatedly extracted with chloroform. In the chloroform solution, levulinic acid and furfural were detected.—A. S.

Mangrove Bark in Queensland; Utilisation of —. Bull. of the Imperial Inst. (Suppl. to the Board of Trade J.), 1905, 2, 276—278.

THE subjoined table gives the results of comparative analyses made on samples of the mangrove bark of Queensland and wattle bark imported from other parts of Australia, the latter being the principal tanning agent at present employed in Queensland:—

	Wattle bark from—			
	Mangrove	Tasmania	New Zealand	South Australia
Moisture	9.35	10.34	9.53	9.46
Total ash	4.78	2.67	2.47	3.33
Soluble ash	1.70	0.96	0.84	1.64
Insoluble matter, &c.	0.75	1.40	0.61	1.80
Total extractive matters	47.90	40.48	38.80	42.49
Tannin	37.50	29.60	27.65	31.25
Non-tannin extractive matter	6.70	9.92	11.96	10.51

Concessions have recently been granted to strip the bark from the trees of the extensive forests of Queensland, and it is probable that, in addition to supplying its own needs, the Colony will be in a position to compete with many of the principal sources from which mangrove is at present exported.—T. F. B.

UNITED STATES PATENT.

Tanning Apparatus. E. G. Steinke, Cincinnati, Ohio. Assignor to the Louisiana Leather Manufacturing Co. U.S. Pat. 780,450, Jan. 17, 1905.

THE apparatus consists of an outer drum containing the

tanning liquor, within which is arranged a smaller inner work drum composed of longitudinal strips, the ends of the outer drum, these strips being projecting inward. The ends of the inner drum are of flats extending to the sides of the outer drum at a distance from the ends of the latter. An agitator apparatus, between the ends of the two drums, the material is arranged to form a chamber in which tannin extracts may be introduced.—A. S.

FRENCH PATENT.

Tanning; Substance for —. E. E. M. P. and E. P. A. 346,404, Sept. 21, 1904. Under Internat. Conv., Oct. 14, 1903.

CHARM is made for a tanning extract containing humors, obtained by the decomposition of vegetable matters. Pent, which is a suitable raw material, is first extracted with a solution of caustic soda or potash, or of sodium carbonate, and the solution obtained is then acidified. A solid extract may be obtained by adding acid until precipitation occurs, and dissolving the precipitate in a solution of a neutral salt, e.g., sodium acetate, when required for use. Other sources of raw materials are waste liquors obtained in the manufacture of paper from wood, and in washing flax thread.—M. C. L.

XV.—MANURES, Etc.

Calcium Cyanamide as a Fertiliser; Employment of —. R. Perotti. Staz. speriment. agrar. ital., 1904, 37, 787—805. Chem. Centr., 1905, 1, 117.

THE author points out that under certain conditions, calcium cyanamide has an injurious influence on the germination of seeds, alters the constitution of the plant tissues, and interferes with the growth of bacteria. To avoid these defects, it should be applied to the soil some time before the seed is sown, and the loss in value caused thereby must be allowed for in reckoning the value of the fertiliser. (See this J., 1903, 800; 1904, 1057.)—A. S.

XVI.—SUGAR, STARCH, GUM, Etc.

Cane Sugar in Official Roots. M. Harlay. J. Pharm. Chim., 1905, 21, 49—55.

THE roots were extracted with boiling 95 per cent. alcohol containing a little chalk, the alcoholic extract was evaporated on the water-bath, the residue taken up with water containing thymol, and a portion of the solution, examined with the polarimeter and with Fehling's solution. Invertase was added to the other portion, which was left for five days at the temperature of the laboratory, and then examined as before. Cane sugar was also isolated and crystallised, after separation as barium sucrate, from the liquors obtained from *Levisticum officinale* Koch, and *Eryngium campestre* L. The results are given in a table. In four cases the optical rotation after inversion did not agree with the deviation calculated from the cupric-reducing power, probably owing to the presence of other sugars in addition to cane sugar. The presence of cane sugar in the roots is general, and in those of the *Umbellifera* the quantity is considerable. The amount of reducing sugar is small, except where vegetative functions are resumed or in the case of old or dried organs.—L. J. DE W.

[*Sugar Juice; Filtration of* —. H. C. Prinsen-Geerhys. Mededeelingen van het proefstation voor suikerriet in West-Java, "Kagok" te Pekalongan, 75, 10—15. Chem. Centr., 1905, 1, 192.

FOR filtering the clear juice obtained by defecation and settling, the author recommends the use of sieves of fine bronze-wire gauze, instead of sand filters.—A. S.

Galactose; Birotation of —. G. Heikel. XXIV., page 156.

Sugar Cane Molasses; Industrial Fermentation of Sulphited —. G. Meunier. XVII., page 145.

ENGLISH PATENTS.

Sugar: Treatment or Preparation of —, T. Shaw, London. Eng. Pat. 28,295, Dec. 24, 1903.

Crystals are made, in the production of "arated" or "basket" sugar, for the preparation and use of a solution of the sugar, and the addition to it of a definite proportion of invert sugar with the object of producing sugar containing preformed proportions of sugar, invert sugar and water, irrespective of the amount of alkaline ash contained in the sugar under treatment; for the rapid boiling of the mixture by forcing it through an externally steam-heated pipe, and for the subsequent rapid formation of very minute crystals. —T. H. P.

Sugar: Treatment or Preparation of —, T. Shaw, London. Eng. Pat. 28,297, Dec. 24, 1903.

THE process is the same as that described in the preceding abstract, but is applied to a solution of raw sugar juice instead of to a solution of sugar. —T. H. P.

Starch, Dextrin or the like: Manufacture of New Products from —, J. Kantorowicz, Preslau. Eng. Pat. 5574, March 7, 1904.

THIS process, which relates to the manufacture of a new modified form of starch, having the valuable property of swelling up with cold water to a viscous liquid like starch paste, consists in treating any convenient kind of starch, soluble starch, dextrin, or the like, in the presence of water, with caustic alkalis and liquids with which starch does not swell up, such as alcohols, acetone, mixtures of alcohol and ether, or the like, and separating the new products after neutralisation. —T. H. P.

UNITED STATES PATENTS.

Sugar Juice: Process of Purifying —, H. Breyer, Kogel, Assignor to A. J. von Wehrstedt, Castle Pinberg, Austria-Hungary. U.S. Pat. 779,261, Jan. 3, 1905.

Additives: Process of Producing —, H. K. Brooks, Fellows Falls, Vt., Assignor to Casein Co. of America, New Jersey. U.S. Pat. 779,583, Jan. 10, 1905.

A LECULA is heated with a solution containing ammonium persulphate and sulphuric acid, with agitation, and the product is rendered neutral or slightly alkaline by addition of borax. —A. S.

FRENCH PATENTS.

Liquids [Sugar Juices, &c.]: Evaporation, Concentration, Distillation and Drying of —, A. Montupet and L. Jannin. Fr. Pat. 339,177, Nov. 21, 1903.

It is an ordinary closed boiling pan, heated by steam coils or tubes, the vapour evolved from the surface of the boiling liquid is withdrawn from the top of the pan by means of an injector working with exhaust or high pressure steam. The mixed vapours are then forced through a pipe into the steam chamber of the boiling pan. In this manner the recuperative principle of the multiple effect system is utilised in a single pan; boiling may be effected under atmospheric or reduced pressure. —J. F. B.

Sweetening Agent: New —, A. H. Tissot. First Addition, dated Sept. 9, 1904, to Fr. Pat. 335,379, Sept. 14, 1903. (See this J., 1904, 197.)

THE "edulcorant porchère" is mixed with gum arabic, tartaric acid and sodium bicarbonate, or with the salts of various mineral waters. —J. F. B.

Levulose from Artichoke Roots: Preparation of Industrial —, J. B. Gaillat. Fr. Pat. 346,469, Sept. 24, 1904.

ARTICHOKE roots are pulped or sliced, and then treated systematically with boiling water, acidified by 0.2 per cent. of hydrochloric or sulphuric acid. The liquid so

obtained is very rich in sugar, which consists of 95 per cent. of levulose and only 5 per cent. of dextrose. —J. F. B.

Finishing Material: Preparation of — [from Molasses, &c.] M. Kowalski. Fr. Pat. 346,355, Sept. 19, 1904. V., page 130.

XVII.—BREWING, WINES, SPIRITS, Etc.

Malts for Different Beers: Requisites of —, W. O'Connor. J. Inst. Brewing, 1904, 10, 530—531.

Moisture.—The usual limit of 3 per cent. is a fair one, but the circumstances should be taken into account. Malt may absorb as much as 1 per cent. of moisture during railway transit for 24 hours, and may thus exceed the limit in spite of excellent conditions of storage. The proportion of moisture is mainly of importance as an indication of the conditions of storage and the alteration of the albuminoids which may follow on damp storage.

Tenderness is a measure of the modification of the endosperm and the accessibility of the starch to the action of the diastase. It is an indication of slow and careful growth, complete withering and skilful kilning.

Time of saccharification is also an indication of the care with which the malt has been prepared; the proportion of ready formed sugars is not a reliable guide.

Appearance of skin.—This is a very deceptive indication of quality, but it may be taken that a bright skin showing the "bloom" of the barley indicates a "forced" malt, since a slow germination destroys the brightness and bloom of the skin.

The considerations affecting the selection of malt for special beers are tint and diastatic power. As regards the latter the most desirable limits appear to be 22—27 (Lintner's scale) for mild ales and stout, and 30—35 (Lintner) for pale ales. —J. F. B.

Water Hardening [for Brewing]. A. W. Rogers. J. Inst. Brewing, 1904, 10, 528—529.

THE typical standard water for pale ales may be taken to have the following composition:—Calcium sulphate, 60; magnesium sulphate, 10; calcium and magnesium carbonates, 20; sodium chloride, 4; total mineral salts, 94, expressed in grains per gallon. If magnesium sulphate be already present in too large a quantity, its proportion can be reduced by adding calcium chloride. When magnesium salts are present in excess the resulting beers are liable to "fret." For mild ales, gypsum and kainite may be added to the brewing water. The salt should be added to the sparging water as well as to the mashing liquor; they should not be added to the grist-case. Waters which contain an excessive quantity of nitrates are improved by boiling with sulphurous acid before use. —J. F. B.

Starch: Diastatic Coagulation of —, J. Wolff and A. Fernbach. Comptes rend., 1905, 140, [2] 95—97.

FURTHER experiments confirm the previous statements by the authors that, when the diastatic coagulation of starch has been once started, it proceeds even when the diastases have been destroyed by heating (this J., 1904, 449). They also come to the conclusion that the state of liquefaction of the starch, which is favourable to the diastatic formation of amylocellulose, is equally favourable to coagulation. The difference in the quantity of amylocellulose formed, on the one hand in the absence of diastase, and, on the other hand, in its presence, becomes the greater according to the degree to which the starch has been heated.

—W. P. S.

Sorbose Bacterium: Biochemical Study of the —, G. Bertrand. Bull. Assoc. Chim. Sucr. et Dist., 1904, 22, 178—180.

SORBOSE does not exist as such in mountain ash berries, but is produced by the oxidation of the sorbitol by the sorbose bacterium. The same bacterium has been utilised for the preparation of several other ketoses from the corresponding polyvalent alcohols; it always attacks one of the secondary alcoholic groups, converting it into a ketone. The following ketoses have thus been pre-

ured:—Dihydroxyacetone, "erythralose," "arabinose," sorbose, levulose, peracose and valenose. Since the ketoses are converted by sodium amalgam into mixtures of two stereoisomeric polyvalent alcohols, one of which is different from the parent alcohol, it is possible to combine the action of the bacterium with that of sodium amalgam and to pass from one alcohol to another, e.g., from sorbitol to *D*-iditol, from *D*-erythritol to *D*-erythritol and from annitol to sorbitol. By a similar combination of actions, an aldose sugar can be converted into a ketose and one ketose into another; e.g., dextrose into sorbose, or levulose into sorbose. The bacterium only oxidises the polyvalent alcohols of a certain stereochemical type, and leaves those of other types unchanged; thus sorbitol can be separated from iditol (compare also sorbicitol, this J., 1904, 1155 and 1905, 37). The bacterium oxidises ketoses by converting them quantitatively into the corresponding monobasic acids; ketoses are gradually oxidised without the production of any characteristic products. When an aldose has been oxidised into the monobasic acid, a subsequent oxidation takes place if a secondary alcoholic group capable of being attacked be present, and a ketonic acid is thus produced, e.g., dextrose converted into oxyglyconic acid.—J. F. B.

Brewery Yeasts; Selection of —, H. W. Watson. J. Inst. Brewing, 1904, 10, 536–538.

PITCHING yeast should be pale in colour, since a dark colour indicates deposits of resins and caramel on the walls of the vials. It should be firm in consistency and show no signs of decomposition; the sedimentary yeast should be caseous in character and not too readily disseminated in beer. A good healthy yeast, the cells are fairly uniform in size, plump, with well defined outlines, and round or slightly oval in shape. Many wild yeasts assume the same shape as culture yeast, and the only reliable test is the spore formation. The protoplasm should be transparent and homogeneous; if it is at all granular, weakness and degeneration are indicated, also accompanied by thick cell-walls and very large vacuoles. Dead cells should be rare; they are stained by the addition of a little Methylene Blue to the preparation. Even good yeast is seldom free from bacteria. If only 3 or 4 bacteria be observed in a complete passage along a diameter of the cover-glass, the sample is sufficiently pure. The sporulation test for wild yeasts should be performed periodically; no spores are formed in 10 days at 10°–11° C., no trouble need be anticipated from wild yeasts. The sample for this purpose should be taken towards the close of primary fermentation, at which stage wild yeasts are most numerous.—J. F. B.

Top-Fermentation Beer Worts [German]; Boiling—Under Pressure. A. Gribat. Woch. f. Brau. 1905, 22, 18.

THE writer has adopted the method of boiling worts for top fermentation in a closed copper under pressure, as is no rule in England in the case of porter worts. Working with the two-mash decoction process and boiling the main wort and after-runnings separately, he first boiled the main wort for half an hour with the copper open and then with the copper closed at a pressure of 14.5 lb. per sq. in., releasing the pressure half an hour before the conclusion of the boiling. In subsequent work he mixed some of the first of the sparging liquors with the main wort in order to fill the copper, and after boiling without pressure until the wort showed a "break," he boiled for 1 hour under a pressure of 20 lb. per sq. in., corresponding to a temperature of 205° C. The results have proved in every way satisfactory, the worts have an extremely good "break," fermentation proceeds quietly with an extraordinarily solid "curly head," and is completed in 4 days. The beer is racked direct from the fermentation tuns to the transport casks and has a pleasant, aromatic flavour, not quite so sweet as formerly. The writer strongly recommends this method of boiling, and would even extend it to bottom fermentation beers, especially those of the Munich type; the increase in the "body-flavour" brought about by boiling the wort under pressure should enable the brewer to brew a wort of lower gravity without loss of quality.—J. F. B.

Fermentation; Relative Production of Alcohol and Carbon Dioxide during —, L. Loubet and P. Moiré. Comptes rend., 1904, 139, 1223–1225.

THE authors have determined the quantities of alcohol and carbon dioxide produced at different stages of primary fermentation. Equal volumes of the same kind of must were sown with equal quantities of the same yeast, the products of fermentation being collected. Different combinations of the latter, made when fermentation had proceeded for different periods, showed that in the first stage the quantity of alcohol produced was distinctly greater than that of the carbon dioxide, whereas, later, the quantities of the two products were practically identical. The temperature of fermentation and the acidity of the must had no sensible influence on the general results. This preponderance of alcohol production over that of carbon dioxide is probably connected with the reproduction of the yeast, since the formation of new cells is practically confined to the first stage of fermentation.—J. F. B.

Attenuation for Different Beers; Requisites of —, W. O'Connor. J. Inst. Brewing, 1904, 10, 539–541.

IN making his calculations the author refers in all cases to beers of an original gravity of 55°, as that is one at which pale, mild and black beers are frequently brewed. Assuming that only the free maltose is attacked during primary fermentation, the subtraction of 11° from the actual gravity at the end of primary fermentation will show the gravity due to malto-dextrins, upon which the cask-condition of the beer depends.

In absence of added sugars ["priming"], the desideratum for pale ales is a "condition" which shall develop slowly during protracted storage, without sacrificing fullness of flavour. For this purpose a wort, rich in high-type malto-dextrins, should be produced, which will attenuate during primary fermentation down to an apparent gravity of 16–19°, leaving malto-dextrins equivalent to 12.5–15° for secondary fermentation. For mild ale, the malto-dextrins should be equivalent to 14° and should be of low type, easily attacked by secondary fermentation yeasts, yielding rapid conditioning and clarification. For stouts, malto-dextrins equivalent to 15° are the rule, and these should be of a type as low as or lower than that of the malto-dextrins in mild ale worts.—J. F. B.

Sugar Cane Molasses; Industrial Fermentation of Sulphited —, G. Mennier. Bull. Assoc. Chim. Sucrière, 1904, 22, 484–486.

WHEN an antiseptic substance, such as sulphite, is present in the wash, its influence can be overcome by increasing the quantity of pitching yeast; in other words, the quantity of antiseptic fixed by a single cell is a function of the number of cells and the weight of antiseptic per litre. The author has determined the number of cells which must be sown in the first pan of a continuous propagating apparatus [Jacquemin's system] in order to arrive at a constant output in a minimum of time, that is, to make it produce equal quantities of yeast cells of a given activity for each fermentation. It was found that for the fermentation of sulphited cane molasses the first propagating pan (200 litres) must be pitched with 3.5–4 kilos of pressed brewery yeast with 70 per cent. of moisture. It is not necessary that the yeast should be acclimatised towards sulphites in the propagating vessels, but the wash in the first pans should be highly acidified (6 grms. of sulphuric acid per litre), the proportion of acid being gradually reduced in subsequent vessels down to 2.5 grms. per litre in the main fermentation tuns. The wash in the propagating pans should be sterilised by heat, and should be mixed with nutrient salts, but the main wash need not be sterilised. Under these conditions 60.5–61 litres of alcohol were obtained per 100 kilos. of reducing substances (calculated as saccharose). The initial concentration of the washes was 110–115 grms. of reducing sugars per litre, 8–10 grms. remaining unfermented. The yeast crop was 15–16 kilos. of pressed yeast per 100 kilos. of molasses, which is about the same as the crop obtained from 100 kilos. of grain. Traces of sulphides were present in the phlegms, but

were easily removed by chlorine water; an abundant evolution of sulphuretted hydrogen was observed in the first fractionation.—J. F. B.

Alcohol and the Detection of its Adulteration.—*Report of Scientific Commission of the French Republic.* 1. Linder, Bull. Assoc. Chim. Sci. et Ind., 1904, 12, 459-471.

The denaturing agent at present employed in France consists of 10 litres of wood spirit and 0.5 litre of heavy (heavy) benzene (specific gravity 1.26) per 100 litres of alcohol, costing 1 franc 50 centes. The Commission has examined a large number of proposed denaturing agents, but the only substance which could be entertained was: 1) Petroleum (b.p. 100-160° C.) mixed with toluene (this mixture has the advantage that it can be detected by H₂O₂ test reaction in all fractions when alcohol containing it is submitted to distillation, a guarantee which the heavy Ex-cise benzene (b.p. 156-250° C.) does not possess, 2) Pyridine, 0.5 per cent., as employed in Germany, 3) Acetone oils from wood-destilling, 4) Formalin.

Tableau des Indications Incompatibles Towards Fraudulent Treatment.—The commonest fraud consists in blending a certain proportion of denatured alcohol with pure alcohol and disguising the flavour by aromatic bodies. The action of formalin in denaturing, to the extent of 0.5 per cent., will still be detected with certainty when the denatured spirit is blended with 15 times its volume of pure alcohol. If the denatured spirit contains 2.5 per cent. of wood spirit, the presence of methyl alcohol can only be detected so long as the blending does not exceed the proportion of 1:8. In order to obtain a higher guarantee against blending, it is desirable that benzene and pyridine or acetone oils should be present. A rarer form of fraud consists in agitating the spirit with benzene or carbon tetrachloride and brine and re-distilling the aqueous portion in a rectifying apparatus. This process yields 60 per cent. of potable alcohol, but requires considerable plant. By this means the whole of the benzene, pyridine and acetone oils are eliminated, but traces of formalin always be detected in the re-natured alcohol, whilst the whole of the methyl alcohol remains. If the re-natured spirit be used for blending purposes, the sole guarantee would rest with the methyl alcohol, which would escape detection at dilutions greater than 1 to 8.

Proposed New Formula for a Denaturing Agent.—The Commission recommends the following mixture:—2.5 per cent. of wood spirit, the methyl alcohol of which serves as an indicator in cases of re-distillation and to a certain limit in those of blending; 0.5 per cent. of formalin (33 per cent. of formaldehyde), mainly as a very delicate indicator in cases of blending and (in the form of traces) in those of re-distillation without subsequent blending; 0.5 per cent. of heavy Ex-cise benzene, together with 0.25 per cent. of pyridine, the flavour of which is very nauseous even at extremely high dilutions, the object of these being to compel the blander (without re-distillation) to employ smaller proportions of denatured spirit in his mixtures. It is calculated that the above mixture would lower the cost of denaturing by 5 francs per hectolitre, and would extend the use of denatured spirits by reducing the price to the small consumer by 5 centimes per litre.—J. F. B.

ENGLISH PATENTS.

Malting Apparatus (Pneumatic Drum). O. Krueger, Berlin. Eng. Pat. 4249, Feb. 20, 1904.

THE processes of germination, drying and kilning are performed in the same drum by dividing the interior of the latter into sections by partitions, either radial or parallel to the axis, each of which sections is again divided into two

unequal chambers, communicating with each other by sliding valves, so that as the malt shrinks on drying, it automatically collects in the larger of the two chambers during the rotation of the drum. The air-pipes inside the drum are so arranged that they form the centres of cooling-zones, and their dimensions are not greater than would correspond to the cooling capacity of the cooled and damped air introduced. In front of the air-pipes are arranged separate pipes which can be used either for heating or cooling, whereby the air is re-warmed or re-cooled after traversing a short distance.—J. F. B.

Brewing, Distilling and like Processes; Apparatus for —. R. H. Leaker, Bristol. Eng. Pat. 4560, Feb. 24, 1904.

THE apparatus consists of two vessels with a pair of fluted crushing rolls interposed between them. Whole malt is charged into the first vessel, which has been previously filled with water at 120-140° F. The malt is washed by agitating with a "rouser"; the water and refuse are drawn off, and a supply of fresh water, at a temperature of 150-160° F., is run in. The malt is saccharified in this vessel, the temperature being maintained by means of a heating coil. After conversion, the mash is passed through the crushing rolls and discharged into the second vessel. It is allowed to remain there for a short time, after which the clear wort is drained off through a perforated bottom. The second vessel is fitted with agitating rakes and a sparger.—J. F. B.

Brewers' Wort: Apparatus for Treating —, for Cooling and other Purposes. J. B. Allott, Nottingham. Eng. Pat. 4651, Feb. 25, 1904.

THIS specification describes apparatus for subjecting brewers' wort to a pressure below that of the atmosphere, access of which to the wort is meanwhile prevented; the froth formed being dissipated so as to release the enveloped steam from the liquid of the froth. The wort may be passed through a series of vacuum pans, the pressures in which are different, and which are so connected that wort is run direct into the pan in which the highest pressure obtains, thence into the next pan for further treatment, and so on. Gradual cooling is effected by causing the same cooling liquid to pass successively through the condensers of the several pans from the last to the first. Claims are also made for cooling wort under reduced pressure, with exclusion of air, and subsequently aerating it by subjecting it to the action of a refrigerator located in a chamber to which air is introduced through a filter so as to render it germless.—T. H. P.

Alcoholic Liquids: Fermentation and Clarification of —. A. van de Kerckhove, Brussels, and A. A. J. Lebbe, Ypres, Belgium. Eng. Pat. 24,994, Nov. 17, 1904.

THE liquids are "fined," and the yeast nutrition is increased, by adding to the wort or must, before fermentation, a certain proportion of "alimentary gelatin," prepared by boiling fresh animal tissues, drying the product and reducing it to powder, this powder being subjected to the action of ozonised air. In the case of beer, the powdered gelatin is preferably added to the wort in the cooler when the temperature is about 90° C. In the case of grape must, the gelatin should first be dissolved and the solution should be added shortly before fermentation.—J. F. B.

Brewers' Grains, other Grain, Seed and the like; Kilns and Machinery for Drying —. S. Dymond, Bristol. Eng. Pat. 5263, March 3, 1904.

IN kilns for drying brewers' grains, &c., where the material is made to take a serpentine course on a series of perforated travelling carriers running round chain pulleys driven by toothed gearing, the following improvements are claimed:—(1) An endless travelling feed conveyor for delivering the grain or other material to be dried, on to the uppermost of the series of carriers, the said conveyor receiving its charge from a magazine fitted with a sliding door, controlling an aperture in the magazine through which the conveyor extends, to discharge on to an inclined plane directing the material on to the carrier. (2) The provision, as part of the construction of the kiln,

of girders extending lengthwise parallel with the carriers. (3) The use of angle irons to bridge over the spaces between the side edges of the carriers and the walls of the kiln. (4) The construction of the stoves or drying chambers with double walls, with an intervening space, and having the apertures for the escape of heat interspaced in the respective walls.—T. H. P.

Must for the Manufacture of Spirits of Wine, the Feeding of Cattle, and the Manufacture of Petrosi; Method of Preparing — W. H. Wheatley, London. From Internat'l Spiritus-Ind. Ges. m.b.H., Berlin. Eng. Pat. 11,113, May 13, 1904.

UNITED STATES PATENT.

Centrifugal Cream-Separator. G. T. Remick, Jr., New York. U.S. Pat. 779,099, Jan. 3, 1905.

IN the drum of the separator are placed a number of superposed radially corrugated division plates, arranged in the liquid space across the radial lines of the drum. Each plate has the shape of a truncated cone, the inner and outer edges of which are curved inward. The corrugations form channels between the plates. Apertures are provided at the middle of the plate, by drawing off the converged edges. A baffle plate is placed above the division plates. Oppositely flowing currents of liquid are thus established between the plates, and each current is directed upwards from the opposite ends to the plates.—W. P. S.

Centrifugal Liquid [Milk] Separator — A. L. Christenson, Stockholm. U.S. Pat. 779,990, Jan. 16, 1905.

THE centrifugal separator-bowl contains a liner consisting of a number of conical plates superposed on each other, and a flanged central inlet-pipe for conducting the full milk through the wall of cream obtained during separating.—T. F. B.

C. DISINFECTANTS.

FRENCH PATENTS.

Gas Sulphur Dioxide for Disinfecting or Lestomphing Purposes: Apparatus for the Production of —. E. Delhotel. Fr. Pat. 346379, Sept. 20, 1904.

SULPHUR is burned on the hearth of a jacketed iron generator, a current of cold air being passed through the jacket, and cold water or air circulated in a vessel arranged within the generator above the hearth. The air to support combustion of the sulphur is drawn from a vessel in which a desiccating agent is distributed on oppositely inclined surfaces. The sulphur dioxide formed is led through purifying columns containing vegetable charcoal, copper turnings, or vegetable fibres, and one of them may contain iron turnings. The gas, thus mechanically and chemically purified, is then brought into contact with a volatile antiseptic liquid (such as formaldehyde), and it may also be mingled with the gas evolved from liquid sulphur dioxide stored in a separate apparatus. An apparatus is described at once aspirative and propulsive by which the gas is drawn and propelled through a cooling arrangement, and may be subsequently injected into the places where disinfection, or the extinction of fire, is required.—E. S.

Antiseptic: A Fluorescent —. E. Turpin. Fr. Pat. 346363, Sept. 20, 1904.

THE substance claimed is resorcinol-phthalein (fluorescein). It may be mixed with perfumes, dentrifices and hygienic products to render them antiseptic, and, if desired, rendered alkaline to enhance its fluorescent properties.—W. P. S.

XIX.—PAPER, PASTEBOARD, Etc.

Wood-Pulp: Poplar —. Wochenbl. f. Papierfab., 1904, 35, 3941—3942.

POPULAR is the only paper-making wood which occurs to any great extent in Italy. The mechanical pulp is not very valuable, it works very "free," and is largely contaminated with splinters owing to the softness of the wood. Large quantities of poplar wood cellulose are, however, manufactured both in Italy and America by the sulphite process. Poplar wood cellulose gives a short-fibred, soft pulp, which does not bleach so white as the best pine cellulose. It is not so suitable as straw pulp for writing paper, being deficient in "rattle." But its special properties make it a good substitute for esparto and cotton, especially in the best sorts of printing papers. A thick, uncalendered sheet takes a very clean impression without much pressure. Poplar pulp carries a large proportion of clay, and in the calendered state answers very well for common writing paper. In combination with 20 or 30 per cent. of cotton, bleached poplar pulp has been used successfully for high-class writing papers, but alone it is too hard and very transparent. For cheap chromo and copper-plate papers it is an excellent material.—J. F. B.

Nitrocellulose: Hygroscopicity of —. W. Will. Mitt. Centralst. f. Wiss.-Tech. Unters., Berlin, 1904, No. 4, 1—33. (See Ome-Masson, this J., 1904, 1143.)

THE author has made an exhaustive study of the influence of the combined nitro groups upon the hygroscopic properties of cellulose. In order to obtain comparative results it was necessary to select two limits representing the two extremes of humidity at which constant equilibria were established. In view of the instability of nitrocellulose at higher temperatures, the author defines his standard of hygroscopicity as the difference between the weights of the materials when dried in an ordinary oven at 40° C. to a constant weight, on the one hand, and when exposed to an atmosphere fully saturated with moisture at a temperature of 25° C. for 24 hours, on the other hand.

Hygroscopicity of various Celluloses and other Carbohydrates.—Raw cottons of different origin, cotton waste and hemp all had the same hygroscopic value of 7.8 per cent.; purified cotton rag-pulp and wood

cellulose showed 6.4—7 per cent. of hygroscopic moisture; jute with 10.8 per cent. and the starches with 10.6—14.1 per cent. were considerably more hygroscopic than the celluloses. Mechanical treatment (pulping) or extraction of the waxes by ether increased the hygroscopicity of the raw cottons to nearly 10 per cent., which may be regarded as approximately the true value for pure cellulose. Treatment with dilute acids and alkalis, on the other hand, decreased the affinity of the cellulose for water, as did also the previous superheating of the cotton above 100° C.

Hygroscopicity of Nitrocelluloses.—The determination of the hygroscopicity of 65 samples of nitrocellulose, prepared from a large variety of different cottons and containing proportions of nitrogen ranging from 13.21 to 8.20 per cent., showed that the sum of the percentage of nitrogen and the hygroscopic moisture was constant in all cases, with a value of about 14.6. This constant remained unchanged by various mechanical, physical and chemical treatments (e.g., pulping, solution or gelatinisation treatment with dilute acids or alkalis, partial elimination of the nitrogen, complete denitration followed by re-nitration). The hygroscopic moisture was found to have no connection with the degree of solubility of the nitrocellulose in ether-alcohol, but depends solely on the percentage of nitrogen. Unstable nitrocelluloses show abnormally high values which, however, are reduced to the normal when the products are rendered stable by long boiling with water.

The accompanying diagram shows the experimental results obtained in the above determinations. The straight line A B illustrates the equation $H = 14.6 - N$

which, however, is only correct within certain limits, which comprise most of the nitrates of industrial importance. Extrapolation values are better expressed by the equation $H = \frac{334.3 - 23.65N}{31.11 - N}$ which takes account

of the variation in molecular weights of the different nitrates, and in which the sum of the hygroscopicity and the nitrogen varies with the proportion of nitrogen; this equation is illustrated by the curved dotted line C D.

Influence of Variations from the Standard Hygroscopicity.—(a) By further drying over sulphuric acid, after drying at 40° C. under ordinary conditions, all the nitrocelluloses lost a further quantity of water; the sum of the hygroscopic moisture and percentage of nitrogen was then no longer a constant, but varied with the proportion of nitrogen to a greater extent. The second equation above was thus changed to $H = \frac{405.8 - 28.7N}{31.11 - N}$.

(b) By varying the temperature at which the products

were exposed to a moist saturated atmosphere from 5° C. to 15° C. and 5° C., while adhering to the ordinary method of drying at 40° C., the hygroscopic moisture was considerably increased, the increase being greater from 25° to 15° C. than from 15° to 5° C. In these cases the sums of the hygroscopic moisture and nitrogen are constants within the practical limits, the equations being $H = 20 - 1.3N$ for 15° C. and $H = 21.6 - 1.4N$ for 5° C.

(c) When the moist equilibrium was established in air at various degrees of humidity, short of saturation, an exposure of 24 hours was necessary before complete interchange was effected. It was found that the ratio between the relative humidity of the air and the hygroscopicity was only constant up to about 80 per cent. of saturation. Between 80 per cent. and complete saturation, the affinity of the nitrocellulose for moisture increased in a far greater measure than the humidity of the air. No constant relation between the percentage of nitrogen and the hygroscopicity of the nitrocellulose could be traced in or below the saturation point.—J. E. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

Hyoxygamas Muticus from India; B. L. S. (Suppl. to the Board of Trade J.), 1905, 2, 222—224.

OF two specimens of *Hyoxygamas muticus* from India, one obtained from the Punjab was found to contain 0.36 per cent. of hyoscyamine in the dry root and 0.38 per cent. in the dry leaves; the second, from Larkana, contained 0.28 per cent. of hyoscyamine; in neither case was any other alkaloid detected. These low alkaloid contents would indicate that the Indian plant could not compete with the richer Egyptian variety as a commercial source of hyoscyamine, and hence of atropine.—T. E. B.

Datura Stramonium from India; S. J. S. (Suppl. to the Board of Trade J.), 1905, 2, 224—225.

A SAMPLE of the seeds of *Datura stramonium*, obtained from Bushahr, India, was found to contain 0.26 per cent. of hyoscyamine, as compared with 0.35 per cent. found in Egyptian and European specimens. As in the case of *Hyoxygamas muticus* (see preceding abstract), there is no other alkaloid present in any of these specimens.—T. E. B.

Harmine and Harmaline, O. Fischer and C. Buck, Ber., 1905, 38, 329—335. (See also this J., 1897, 1036.)

WHEN harmic acid is heated it loses two carboxyl groups and is converted into apoharmine; when the acid is heated under pressure at 200° C. with concentrated hydrochloric acid it loses only one carboxyl, yielding apoharmine-monocarboxylic acid in the form of the hydrochloride. This substance has both acid and basic characters, it is decomposed at a temperature of about 330° C. with formation of apoharmine. Apoharmine-monocarboxylic acid yields both methyl and nitro derivatives.

Nitroapoharmine contains the nitro group in combination with a carbon atom; when reduced by tin and hydrochloric acid it is converted into amino-apoharmine; it also yields a methyl derivative when treated with methyl iodide.

Dihydroapoharmine forms a well characterised picrate, melting at 198° C. which salt is of great assistance in the preparation of the pure base. Harmine, when carefully warmed with acetic anhydride and sulphuric acid, yields no acyl derivative, but is converted into *harmine-sulphonic acid*, in which the sulphonic group is attached to a nitrogen atom, which is additional evidence of the secondary nature of the base.—J. E. B.

Isophysostigmine, Ogiu, Apoth.-Zeit., 1904, 19, 891. Pharm. J. 1905, 74, 76.

THE author has examined isophysostigmine, which was found by Merck accompanying physostigmine in Calabar beans. The two bases have the same chemical composition. Physostigmine is soluble in ether, and gives no precipitate when a 1 per cent. aqueous solution of its sulphate is treated with platinum chloride. Isophysostigmine, on the other hand, is insoluble in ether, and forms a crystalline chloroplatinate when a 0.5—1 per cent. solution of its sulphate is treated with platinum chloride. Isophysostigmine sulphate melts at 202° C., physostigmine sulphate at 140°—142° C. The physiological action of the two bases is similar in character, but 0.75 mgrm. of isophysostigmine produces the same effect as 1 mgrm. of physostigmine.—A. S.

Siberian Fir (Pichta; Abies Sibirica); Crystalline Products of the Essential Oil of—P. Golubev, J. russ. phys.-chem. Ges., 1904, 36, 1096—1108. Chem. Centr., 1905, 1, 95. (See this J., 1903, 879.)

THE essential oil of *Abies sibirica* contains two crystalline compounds, *viz.*, *l*-bornyl acetate (43.96 per cent.) and *l*-camphene (about 10 per cent.). The *l*-bornyl acetate

was isolated in the form of rhombic crystals melting at 20° C. and boiling at 223–224° C. at 758 mm. As regards rotation, in alcohol solution $[\alpha]_D^{20} = +15.47$ (20° C.) with $c = 15.5$, and $[\alpha]_D^{20} = +16.0$ with $c = 19.6$. The *l*-bornolide, isolated and melted at 204° C. and boiled at 216° C. at 773 mm.; in alcohol solution $[\alpha]_D^{20} = +36.14$ (20° C.) with $c = 15.22$ and $[\alpha]_D^{20} = +37.77$ (20° C.) with $c = 15.10$. *l*-Bornol, when oxidised with nitric acid of sp. gr. 1.4, or by a mixture of chromic and dilute acetic acids, is converted into *l*-camphor, $C_{10}H_{16}O$, m. pt. 188–189° C., b. pt. at 757 mm., 204° C.; $[\alpha]_D^{20} = +41.41$ in alcoholic solution with $c = 9.97$ and $t = 20^\circ$ C. This *l*-camphor closely resembles ordinary camphor. The *l*-camphene, $C_{10}H_{16}$, from essential oil of *Thescl'ieria*, solidifies at 38–39° C., melts at 40–41° C., boils at 159–160° C., and $[\alpha]_D^{20} = +85$ with $c = 1.76$ and $t = 18^\circ$ C. (See also this J. 1904, 336 and 1042.)—A. S.

Peppermint Oil; *Java* —, P. Vander Wielen, Pharm. Weekbl., 1904, 41, 1084–1084; Chem. Centre, 1905, 1, 95.

The essential oil of Java peppermint (*Mentha pycnantha*) has a pleasant odour different from that of ordinary peppermint, a faint bitter taste, and a bright green colour. It has the sp. gr. 0.9244 at 15° C., $d_4^{15} = +4.41$, 100 mm. tube, and is soluble in 1.5 vols. of 70 per cent. alcohol. The oil contains a considerable quantity of pulegone, but little or no menthol and menthone.—A. S.

Cajuput Oil; *Green Colour of* —, H. C. Prinsen-Geerlings, Chem. Weekbl., 1904, 1, 931–934; Chem. Centre, 1905, 1, 95.

The characteristic green colour of cajuput oil is stated to be due to the presence of copper, kept in solution by the butyric and valeric acids and esters of the same contained in the oil. If specimens of cajuput oil freed from acids and esters, benayed with water and with ethyl formate, acetate, propionate, butyrate, valerate, lactate, citrate, cinnamate, and oxalate respectively, together with a few drops of the corresponding acid, and the whole allowed to act on copper turnings, only those samples of oil containing butyrate and valerate are coloured; in all other cases the dissolved copper is found in the aqueous layer. Valerian oil, when left in contact with copper turnings, also acquires a green colour, and is not decolorised by agitation with water.—A. S.

Acetylene Tetrachloride; *Process for Producing* —, P. Askenasy and M. Mugdan, Nuremberg, Germany. Eng. Pat. 18,602, Aug. 27, 1904.

ACETYLENE and chlorine are successively passed into cooled antimony pentachloride; the first product is $SnCl_4$, C_2H_2 , which readily and smoothly absorbs 4 atoms of chlorine, acetylene tetrachloride (tetrachloro-ethane) being formed. The reaction may be made a continuous

one, since even when the antimony pentachloride is ve considerably diluted by acetylene tetrachloride, the reaction still takes place sufficiently rapidly. The acetylene and chlorine may be introduced simultaneously into the antimony pentachloride, which should then be contained in two separate, but communicating vessels. The acetylene tetrachloride is isolated from the reaction product either by fractional distillation or by decomposing the antimony pentachloride with water or hydrochloric acid. Acetylene tetrachloride is an excellent solvent for oils, fats, resins, &c.—T. F. B.

UNITED STATES PATENTS.

Sesquiterpene Alcohol [*Perfume*]; *Process of Making* —, M. Kerschbaum, Assignor to Chem. Fabr. zu Holmünden Ges. m. b. H., Holmünden, Germany. U. S. Pat. 775,978, Nov. 29, 1904.

A SESQUITERPENE alcohol, of the formula " $C_{15}H_{26}O$," obtained from essential oils of cassia or of ambrette seed, and also from certain other essential oils, by treatment with anhydrides of organic acids, e.g., phthalic anhydride. The oil is first treated with dilute alkali and fractionated; the fraction distilling between 150° and 200° C. (and 20 mm. pressure), being treated with the anhydride; the mixture is distilled, the crude ester is decomposed with alkali, and the product distilled with steam. The distillate is then fractionated under reduced pressure, the portion boiling between 155 and 165° C. (10 mm. pressure) constituting the pure alcohol. It is a colourless oil, soluble in organic solvents; of b. pt. 160° C. (10 mm., uncorrected); sp. gr. = 0.885 at 18° C., and $N_D^{20} = 1.488$. On oxidation with chromic acid it is converted into a aldehyde, the semicarbazone of which melts at 133–135° C. The new alcohol is said to have a pleasant floral odour, and is suitable for the preparation of perfume (Compare Fr. Pat. 326,658 of 1902; this J., 1903, 819).—T. F. B.

Chloral-Acetone-Chloroform and Process of Making same —, C. F. Schaerger, Assignor to the Firm of F. Hoffmann, Laroche, Basle, Switzerland. U.S. Pat. 778,277, Dec. 27, 1904.

CHLORAL-ACETONE-CHLOROFORM is produced by heating molecular proportions of chloral and "acetone-chloroform," and re-crystallising the resulting mass from suitable solvent. It is a solid of m. pt. 65° C., and capable of sublimation without decomposition; possesses a faint odour and taste resembling camphor, sparingly soluble in cold water, and easily soluble in dilute alcohol; it is decomposed by sulphuric acid into chloral and acetone-chloroform, and reduces hot potassium permanganate solution. Its composition is given as $C_6H_8O_3Cl$.—T. F. B.

Acetylsalicylphenetidine; *Process of Making* —, S. I. Summers, Philadelphia. U.S. Pat. 778,556, Dec. 27, 1904.

ACETYLSALICYL-*p*-PHENETIDINE is produced by the action of "an acetylsalicylic acid compound" on *p*-phenetidine in presence of xylene; the mixture is heated until solution is complete, and the crude product which separates on cooling is purified. (See also U.S. Pats. 706,355 and 706,356 of 1902; this J., 1902, 1154.)—T. F. B.

α - β -Methylionone and Process of Making same —, R. Schmidt, Holzmünden, Germany. U.S. Pat. 779,187, Jan. 3, 1905.

METHYLIONONE is heated with a solution of bisulphite and the oil which is insoluble is purified. The α - β -methylionone thus obtained, is a fragrant liquid, suitable for use in perfumery and for flavouring food products; it has a b. pt. of 135–140° C. (20 mm.); sp. gr., 0.931, and refractive index 1.5003 at 20° C. Its semicarbazone melts at 202° C., and its bromophenylhydrazone at 124–125° C.—T. F. B.

Bornyl Esters and Process of Making Camphor, &c. —, B. Seifert, Radebeul, and C. Philipp, Dresden, Assignors

to Chem. Fabr. von Heyden. Act.-Ges., Rad heim, Germany. U.S. Pat. 779,377, Jan. 3, 1905.

Eng. Pat. 26,785 of 1903; this J., 1904, 204.—T. F. B.

oxidising Methyl Groups in Aromatic Hydrocarbons; Process of —. M. Bazlen and H. Labhardt, Assignors to Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. U.S. Pat. 780,401, Jan. 17, 1905.

Eng. Pat. 17,982 of 1903; this J., 1904, 910.—T. F. B.

alkylbarbituric Acid; Process of Making —. K. Stephan and P. Hunsalz, Assignors to Chem. Fabr. auf Actien, vorm. E. Schering, Berlin. U.S. Pat. 780,421, Jan. 17, 1905.

ALKYLBARBITURIC acids are produced by oxidising the corresponding dialkylmalonylguanidines in acid solution. The process of preparing diethylbarbituric acid is specially aimed.—T. F. B.

FRENCH PATENTS.

alcohols and their Derivatives; Production of new Industrial Compounds —, and General Method for Preparing Primary Alcohols. L. Bouveault and G. Blanc. First Addition, dated Nov. 18, 1903, to Fr. Pat. 338,895, June 27, 1903. (See this J., 1904, 798.)

DIMETHYLOCTANOL and 3,7-dimethyloctene-4-ol are prepared by reducing dimethyl-3,7-octenoic ester and methyl-3,7-octadiene-2,4-oic ester respectively with lithium and absolute alcohol. These esters are prepared by condensing the corresponding methylheptanone or thylheptenone with iodoacetic ester, and dehydrating the resulting compound. This method can be extended to the preparation of other analogous alcohols. 5,9-methyl-4,8-decadienol is produced by the reduction of cyrideneacetic ester, whilst a homologous alcohol, containing two more carbon atoms, results from reducing a condensation product of citral and acetoacetic ester. Instead of preparing alcohols, as in the original patent, by reducing the esters of the corresponding acids, they may be prepared by reducing (with sodium and absolute alcohol) the corresponding acid amides, $R.CO.NR'_2$, where R' represents hydrogen or an alkyl radical. The necessity for using perfectly dry amides and absolutely hydrous alcohol is emphasized.—T. F. B.

rimidine; Process for Producing Cyano-derivatives of —. Maison E. Merck. Fr. Pat. 346,188, Sept. 3, 1904. Under Internat. Conv., Sept. 15, 1903.

By condensing dicyanodiamide with acetoacetic ester, clonic esters, or cyanoacetic esters, or their substitution derivatives, in presence of alkaline condensing agents, cyanamino-6-hydroxypyrimidine derivatives are obtained. For example, 2-cyanamino-4-methyl-6-hydroxypyrimidine is obtained from acetoacetic ester by condensation with dicyanodiamide in presence of sodium hydroxide.—T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

aminophenol Soda as a Developer. E. Valenta. Phot. Korr.; through Brit. J. Phot., 1905, 52, 28.

REBEL's statement that the addition of three molecules of caustic soda to a solution of diaminophenoldihydrochloride (i.e., sufficient to produce the sodium salt of diaminophenol) gives a rapid developer, producing images quite free from fog, is declared to be erroneous, since such a solution is found to fog the plate immediately. The best result was obtained by the addition of two mols. of caustic soda, i.e., sufficient to liberate the free base, by further addition at once rendering the developer useless on account of the fog produced. Owing, however, to the rapidity with which such a developer oxidises, it is found best, for practical purposes, to use a developer in which only one of the hydrochloric acid groups was neutralised, the composition being diaminophenol, 5 grms.; sodium sulphite (crystals) 10 grms.; caustic soda solution

(1 per cent.) 100 c.c.; water 900 c.c. Such a developer remains clear, works rapidly, and gives other results than the ordinary amidol developer.—T. F. B.

Thiocarbamide Toning Bath; The —. Kessler. Brit. J. Phot., 1905, 52, 28.

PRINTS toned by means of a solution of gold chloride and thiourea are found to be quite as permanent as those toned by any other gold or other toning bath. The solution recommended is made by adding a 2 per cent. solution of thiourea to 25 c.c. of a 1 per cent. gold chloride solution, until the precipitate first formed is redissolved (14 to 15 c.c. are necessary). 0.5 gm. of citric acid is then added, and the solution made up to 1 litre. Toning takes place very rapidly, and the prints should be well washed before immersion in the bath. Brownish-red to blue-violet tones are obtainable according to the duration of treatment.—T. F. B.

Silver Image Toned with various Metals; Composition of the —. A. and L. Lumière and A. Seyewetz. Brit. J. Phot., 1905, 52, 68—69.

THE coloured silver images, obtained by toning negatives with uranium, iron and copper salts, were examined. The toning baths all contained potassium ferrioxanide, the other constituents being uranium nitrate, ferric citrate and cupric chloride respectively. The images were all found to contain small quantities of potassium, due to incomplete decomposition of the ferrioxanide. Rejecting this potassium content, the images appeared to consist of substances of complex composition, and not closely related to one another. Thus, the uranium-toned image appeared to have a composition intermediate between those represented by the formulae $Fe.Ag_3UO_2(CN)_6$ and $[FeAgUO_2(CN)_6]:UO_2$; similarly the iron-toned image appeared to lie between $Ag_2Fe_2'''Fe_2'''(CN)_{12}$ and $Fe_3'''Fe_2'''(CN)_{12}$, and the copper image between $[Fe.Cu.Ag(CN)_6]_2 = Cu$ and $FeCu_2(CN)_6$.—T. F. B.

ENGLISH PATENTS.

Colour Photography. A. Lezeckiel, Berlin. Eng. Pat. 4941, Feb. 29, 1904.

THIS invention relates to the production of photographs in natural colours from an ordinary negative, by printing upon a specially prepared paper or transfer tissue. This latter is prepared by coating a suitable support with successive layers of sensitised gelatin, coloured with different pigments, the order in which these layers are placed depending upon the actinic intensity of the light reflected by the different colours in the object photographed. For example, in landscape photography, the sky provides the predominating high lights, so the blue film is placed uppermost in a very thin layer; the light yellow parts come next in intensity, so the yellow layer is placed under the blue one, and is of somewhat greater density than the latter. In order to avoid confusion of colours, a layer of gelatin of a colour complementary to the blue is interposed between the latter and the yellow layer. For general landscape work, the following order of films is found to be best:—Blue, pink or crimson, yellow, red, green and black, the black layer being adjacent to the support. After printing, the paper is transferred to a second support, and developed in warm water, after which it may be transferred to a "permanent support." As a general rule, it is stated that each layer should be so thick as to prevent the layer beneath it from showing through it in single transfer work, and so powerful (as regards colour) as to prevent the layer below from being visible through it in double transfer work.

—T. F. B.

Photographic Images or Prints; Manufacture of Coloured —, and of Sensitive Surfaces therefor. O. Imray, London. From Farbwerke vorm. Meister, Lucius und Brüning, Hoechst-on-the-Maine, Germany. Eng. Pat. 4994, Feb. 29, 1904.

It is found that the leuco-compounds of organic dyestuffs, when mixed with a substance containing a nitro- or nitroso-group that can be easily eliminated, are oxidised to the corresponding dyestuff on exposure to light. This

is applied to the preparation of paper, &c., for use in preparing coloured photographic prints. For example, 0.4 gram. of "leu cambrac" is dissolved in 20 grms. of alcohol, and 20 grms. of 0.5 to 50 grms. of 1 per cent. collodion are added, and the mixture applied to paper, and allowed to dry. The image is "fixed" by dissolving out the uncoloured leuco compound by means of an aromatic hydrocarbon, chloroform, trichloroacetic acid, &c. The sensitiveness of such papers is considerably increased by the addition of some oxygen carrier, such as platinum chloride, turpentine oil, or quinoline. By this process, leucamine yields a red image, hexamethyl- β -naphthol a blue-violet image, the leuco bases of the Meltzer Green series green to blue images, and those of El vaniline, Uranine, &c., yellow images. Suitable compounds for mixing with the leuco-stuff are nitro-carbohydrates, such as nitrocellulose or nitroglucose, and nitrosalts, such as phenylmethyl- or diphenylnitrosamine. (T. F. B.)

Colour Photographs on Sensitized Papers and Papers. — See *Annales des Ploques et Papiers Photographiques*, A. Lamière et ses Fils, Lyon-Monplaisir, France. Eng. Pat. 25,718, Nov. 25, 1904. Under Internat. Conv., Jan. 13, 1904.

This specification constitutes an addendum to Eng. Pat. 22,988 of 1904 (see this J., 1905, 104). The coloured particles for preparing the plates may consist of a mixture of red, yellow, and blue particles (with orange, green and violet as well, if desired), or a mixture of these with any other coloured particles may be employed. Two layers of such particles are not absolutely necessary; the desired result may be obtained by coating the plate with a layer having at no point of its surface any superimposed particles. The coating may also be formed of particles of different sizes; the larger particles may be applied first, and the smaller ones dusted on subsequently in such a manner as to fill up the interstices between the larger particles; these smaller particles may be of similar colours to the larger ones, or they may be of any other colour, even black. (T. F. B.)

Photographic Printing Papers of the Class known as Self-toning Printing Out Papers: Manufacture of — E. C. Morgan, Richmond. Eng. Pat. 26,247, Dec. 2, 1904.

If, instead of using gelatin or collodion for preparing the emulsion for "self-toning" printing out papers, a mixture of arrowroot and agar-agar be employed, the gold salt is found to be more easily reduced on immersion in the "hypo" solution. The emulsion may be prepared as follows:—6 drms. of sugar, 5 drms. of citric acid, 64 grs. of ammonium chloride and 4 drms. of Rochelle salt are dissolved in 24 oz. of water containing 1.5 oz. of arrowroot or other starch. The following solutions are then added:—9 drms. 36 grs. of silver nitrate in 8 oz. of water; 11 grs. of gold chloride in 6 oz. of water; 2 drms. of agar-agar in 18 oz. of water. The paper is coated with this emulsion, and subsequently treated in the usual manner. (T. F. B.)

Nitrocellulose; Hygroscopicity of — W. Will. XI² page 148.

ENGLISH PATENT.

Explosives; Manufacture of — J. Y. Johnson. London. From Soc. Anon. des Poudres et Dynamit Paris. Eng. Pat. 25,797, Nov. 26, 1904.

SOLID nitro derivatives of toluene when dissolved nitroglycerin are stated to lower its freezing point to -20°C . without altering its sensitiveness and stability. A mixture of solid dinitrotoluene (80 per cent.) and trinitrotoluene (20 per cent.), constitutes after fusion a liquid mixture which answers the same purpose as each of the solid constituents, and claim is made for this liquid mixture in explosives containing nitroglycerin. (See a Fr. Pat. 333,502; this J. 1903, 1367.)—G. W. McD.

UNITED STATES PATENTS.

Nitrated Starch; Process of Making — F. B. Holm Woodbury, N.J., Assignor to The Eastern Dynamite Co., Wilmington, Del. U.S. Pat. 779,421, Jan. 10, 1905.

A STABLE nitrated starch is produced by nitrating starch separating the nitro compound from the acids, and boiling it in the presence of an insoluble substance (calcium carbonate) capable of neutralising acid.—G. W. McD.

Nitrated Starch; Process of Making — F. B. Holm Woodbury, N.J., Assignor to The Eastern Dynamite Co., Wilmington, Del. U.S. Pat. 779,422, Jan. 10, 1905.

NITROSTARCH is rendered stable by dissolving it in a mixture of alcohol and a solvent having a lower evaporating point than alcohol (acetone), evaporating off the acetone and separating the nitrated starch from the alcohol.

—G. W. McD.

Explosive. — C. E. Bichel, Hamburg, Germany. U.S. Pat. 779,760, Jan. 10, 1905.

SEE Fr. Pat. 325,507 of 1902; this J., 1903, 710.—T. F.

Match Composition. — H. Staier, Brooklyn, N.Y. U.S. Pat. 779,674, Jan. 10, 1905.

THE composition consists of scarlet phosphorus (20 parts), powdered sulphur (6 parts), potassium chlorate (90 parts), powdered glass (42 parts), plaster of Paris (8 parts), zinc oxide (8 parts), whiting (4 parts), and glue (32 parts).—G. W. McD.

XXIII.—ANALYTICAL CHEMISTRY.

INORGANIC—QUALITATIVE.

Manganese; Testing with Potassium Permanganate, Zinc Oxide used for the Quantitative Determination of — L. L. de Koninck. Rev. Univ. des Mines, 1904. Chem. Zeit., 1905, 29, Rep. 5.

TWO to three grms. of the zinc oxide are carefully triturated with 20–30 c.c. of water containing 0.5–1.0 gm. pure iron alum in solution. The mixture is then dissolved by agitation in a sufficient quantity of 6N-sulphuric acid, added by degrees, excess being avoided. A single drop of permanganate solution should suffice to color the liquid a decided pink; but if the oxide contains metallic zinc or zinc sulphide, the reduction of the iron thereby to the ferrous state will lead to decolorisation of the permanganate. —C. S.

rium and Strontium; Detection of Small Quantities of —. L. Blum. *Z. anal. Chem.*, 1905, 44, 9–10.

The presence of small quantities of barium and strontium may easily be overlooked in qualitative analysis, owing to their being precipitated as sulphates by the ammonium phosphate almost invariably present in yellow ammonium sulphide used for the precipitation of the iron group. It is, therefore, of especial importance to use freshly prepared ammonium sulphide, and also to examine for barium and strontium the residue left after the sulphide precipitate has been dissolved.—T. F. B.

ferrous Oxide in Presence of Ferric Oxide; Detection of —. L. Blum. *Z. anal. Chem.*, 1905, 44, 10–11.

TEMPTS to apply the well-known ferrous sulphate and phosphoric acid test for nitric acid to the detection of ferrous salts, failed, owing to the mixing of the nitric and sulphuric acids. It was found, however, that the detection could be easily carried out by adding to the solution to be tested an equal volume of concentrated phosphoric acid, and introducing a large crystal of potassium nitrate into the mixture. The presence of ferrous salt is manifested by the appearance of a red brown coloration of the solution near the crystal. When considerable quantities of a chloride are present, it is well to boil the solution and then cool it previous to adding the potassium nitrate.—T. F. B.

in the Stannous State; Detection of —. L. Blum. *Z. anal. Chem.*, 1905, 44, 11–12.

THE method described in the preceding abstract for detecting ferrous compounds may be applied indirectly to the detection of stannous compounds. A small quantity of ferric chloride solution is added to the solution to be tested, and the mixture tested for ferrous compounds by the method described above. A coloration would indicate the presence of a stannous compound, which had reduced the ferric chloride to the ferrous state.—T. F. B.

INORGANIC QUANTITATIVE.

Palladium-Hydrogen; Use of — as a Reducing Agent in Quantitative Analysis. A. C. Chapman. *Analyst*, 1904, 39, 346–357.

THE applicability of palladium-hydrogen as a reducing agent for the quantitative analysis of various inorganic salts was examined. The palladium-hydrogen was prepared by soldering pieces of palladium foil, 2 in. square, and weighing 8 grms., to stout palladium wire, and charging the metal with hydrogen electrolytically in a solution of sulphuric acid. Solutions of ferric salts, containing about 0.1 gm. of iron, acidified with sulphuric acid, were completely reduced to the ferrous condition by boiling with the palladium-hydrogen for about 20 minutes; the presence of aluminium salts and of phosphates in no way interferes with the accuracy of the process. Acidified solutions of chromates were completely reduced to the corresponding chromic salts in a similar manner. Dilute, acidified solutions of cupric salts were similarly completely reduced to cuprous salts by palladium-hydrogen, the copper being determined by precipitation as thiocyanate, and then weighed as such, or as sulphide. When "unburdened," palladium is boiled in acid solutions of ferric or cupric salts, reduction to the ferrous or cuprous salts occurs, with formation of palladium chloride. Alkaline solutions of ferric ferriyanide (about 0.2 gm.) were completely reduced to ferrocyanide by boiling with palladium-hydrogen for about 20 minutes. Excess of alkali is to be avoided, and the treatment should not be unduly prolonged. Ceric salts in acid solution were also completely reduced to cerous salts. Only very dilute solutions of potassium permanganate could be reduced by this method. The reduction of potassium chlorate by palladium hydrogen was always imperfect, the results varying between 47 and 94 per cent. of theory. Perchlorates, bromates, iodates, mercuric and stannic salts and arsenic acid were only very slightly reduced, and

only 10 per cent. of the nitrogen of potassium nitrate was converted into ammonia by palladium-hydrogen. In the case of vanadium and molybdenum salts, the reduction is of an indefinite character, proceeding to the formation of vanadium tetroxide and molybdenum dioxide respectively, but not ceasing sharply at a point corresponding to the formation of a lower oxide.—T. F. B.

Manganese as Sulphide; Determination of — in Manganese Ores containing Barium. L. Blum. *Z. anal. Chem.*, 1905, 44, 7–9.

IN the precipitation of manganese sulphide by means of yellow ammonium sulphide, some barium sulphate is precipitated by the sulphate existing as impurity in the ammonium sulphide solution, if the manganese ore contain barium, as is the case with most Brazilian, Spanish and Indian ores. It is proposed, therefore, to add a small quantity of dilute sulphuric acid to the manganese solution before precipitating the iron and alumina as basic acetates. Emphasis is also laid on the desirability for using freshly prepared ammonium sulphide for the precipitation of the manganese.—T. F. B.

Gold Assaying; Note on the Influence of Fine Crushing on the Assay Value. A. Whithy. *J. Chem., Metall. and Mining Soc. of S. Africa*, 1904, 5, 95.

THE author brings evidence to show that very finely crushed material gives higher results on assay by fusion than does the same material when less finely crushed. He recommends the 100 linear mesh as a sort of standard. In the discussion, some speakers thought that adequate fluxing and the addition to the fused mass of a mixture of litharge and charcoal (reduced lead)—termed "washing" the slag—was of more importance than fine grinding of sample.—J. H. C.

Antimony and Tin; Electrolytic Determination and Separation of — from Solutions of their Sulpho-salts, together with a Study of the Determination of Antimony by the Trisulphide Method. A. Fischer. *Z. anorg. Chem.*, 1904, 42, 363–417.

ELECTROLYTIC methods for the determination of antimony and tin from solutions of their sulpho-salts have the disadvantage that polysulphides are formed which exert a solvent action on the deposited metal. In order to avoid the complicated process recommended by Ost and Klapproth (this J., 1900, 911; 1901, 1028) to overcome this difficulty, the author has tried the addition of reducing agents to the electrolyte, and has found that satisfactory results can be obtained by addition of sodium sulphite or hydrosulphite (hyposulphite) or especially potassium cyanide in the determination of antimony in sodium sulphide solution, and of sodium sulphite in the determination of tin in ammonium sulphide solution. It is preferable to use platinum-iridium instead of platinum anodes. In the determination of tin, a uniform separation can only be effected if the platinum cathode be coated with tin; this is best done by depositing on the platinum, first a thin coating of copper from a hot oxalic acid solution, and then a coating of tin from an ammonium binoxalate solution rendered acid with oxalic acid. The separation of antimony and tin can be effected from sodium sulphide solution saturated at 20° C. if potassium cyanide be added to the electrolyte, which must also contain 2–4 grms. of free sodium hydroxide. The temperature should not exceed 20° C. and the E.M.F. must not be greater than 1.1 volts. Trivalent antimony may be separated from tin without the addition of potassium cyanide. In this case, the electrolyte is a solution of sodium sulphide saturated at 50° C., and the E.M.F. should not exceed 0.9 volt. The cause of the higher results obtained in the determination of antimony by the electrolytic method than by the gravimetric trisulphide method, is that the composition of the antimony trisulphide does not correspond exactly to the formula Sb_2S_3 . A specimen of the trisulphide prepared with great care by the author contained 27.98 per cent. of sulphur instead of 28.58; and 72.03 per cent. of antimony instead of 71.42.—A. S.

Carbon Monoxide in Confined Atmospheres: Determination of —. A. Levy and A. Pecoul. *Comptes rend.* 1905, 140, 98—99.

The authors employ a method based upon the reduction of antimony chloride acid by carbon monoxide. The "thermal volume" is received in about 4 c.c. of pure methyl alcohol, by comparing the depth of colour of the pink solution obtained with that yielded by known amounts of methane, the quantity of carbon monoxide in a given volume of air may be ascertained. The presence of 1,200,000 of carbon monoxide can be determined by this method, the volume of air required being 4 litres. A small quantity of water may be placed on the surface of the chloroform to prevent evaporation of the latter. —W. P. S.

Mercuric Chloride: Volatility of —, in Aqueous Solution. A. Minicci. *Boll. Chim. Farm.*, 1904, 43, 745—747. *Chem. Centr.*, 1905, I, 70—71.

The author found that on distilling 300 c.c. of a 0.1—1 per cent. solution of mercuric chloride with steam, so that one-half distilled over in 40—45 minutes, the distillate contained from 0.00025 to 0.0022 gram. of mercuric chloride. The quantity of mercuric salt carried over increases with the concentration of the solution, and the error introduced into analysis under these conditions may amount to 0.2 per cent. Similar results were obtained with mercuric chloride solutions in presence of hydrochloric acid (3.5 grms. in 300 c.c.), and of phosphoric acid (c.c. of sp. gr. 1.75) and sodium chloride (5 grms.), but in presence of phosphoric acid alone, the volatility of the mercuric chloride appeared not to appreciably increase with the concentration of the solution. —A. S.

ORGANIC—QUALITATIVE.

Formaldehyde: Detection of —, in Spirit Denatured with Formalin. L. Lindet. *Bull. Assoc. Chim. Sucri.* et Dist., 1904, 22, 475—477.

THE proposed decrease of the proportion of wood-spirit in French denatured alcohol (see page 146) has necessitated the introduction of formalin as a delicate indicator for the detection of fraud. The most certain method for the detection of formaldehyde is that of Trillat (condensation with dimethylaniline at the temperature of the water-bath, extraction of the base with ether and oxidation by lead peroxide). As a rapid preliminary test, the author prefers, however, the following modification of Eury's test (*Ann. de Chim. analyt.* 1904, 254):—10 c.c. of the spirit are placed in a test glass and a pinch of dry casein is introduced. A few drops of a dilute solution of ferric chloride are added, then 10 c.c. of syrupy phosphoric acid and, finally, 10—15 c.c. of sulphuric acid. If formaldehyde be present a violet coloration appears at once, whilst in absence of formaldehyde, the coloration is brown. This test is capable of detecting 1 part of formaldehyde in 300,000 of spirit. Acetaldehyde gives no coloration, but if the proportion be large, the mixture turns black; such samples should be diluted. Certain higher aldehydes, such as butyric and valeric aldehydes, appear to yield the violet coloration, but these are never present in the "head products" of distillation, which alone are used for denaturing. —J. F. B.

Archil, Cudbear and other Lichen Colours: Note on the Detection of —. L. M. Tolman. *J. Amer. Chem. Soc.*, 1905, 27, 25—26.

COLOURING matters from lichens such as archil and cudbear are frequently used for colouring medicines and foods where coal-tar dyestuffs are prohibited. For distinguishing between these two classes of dyestuffs, the ammoniacal solution of the material under examination is extracted with amyl alcohol, in which the natural colouring matters of fruits and wines are insoluble. The amyl alcohol extract is evaporated, and the residue tested by dissolving in water and reducing with tin and hydrochloric acid. Lichen colouring matters are decolorised, but are reproduced by oxidation with ferric chloride, and can in this way be distinguished from Magenta and azo dyestuffs. —A. S.

Bacillus Coli Communis: Neutral Red Reaction for —. E. W. Moore and C. Revis. *J. of Pathol. and Bact.* 1904, 10, 97—104.

Is working with the Neutral Red reaction for *Bac. coli communis*, with broth containing glucose, according to the directions of Savage (*J. of Hyg.*, 1901, 1, 437), the authors failed to obtain satisfactory results, even with undoubted cultures of the *Bac. coli*. By using broth without the addition of glucose, good results were obtained, and it was found that whilst the reaction only takes place in the broth contain "respirable material" of some kind, broth which is free from such material is not rendered suitable by addition of glucose. Addition of lactose, was however, found to give satisfactory results in all the types of media used, viz., neutral and alkaline broth prepared from meat and from commercial meat extract. The use of lactose also affords a means of distinguishing between *Bac. coli communis* and *Bac. enteritidis* (Gaertner) since in broth containing no "respirable material" other than lactose, Gaertner's bacillus would not give the Neutral Red reaction. —A. S.

Saccharin: Detection of —. E. v. Mahler. *Chem. Zeit.*, 1905, 29, 32.

For the detection of saccharin, especially in presence of salicylic acid, the author recommends warming the substance under examination with metallic sodium, potassium, and testing the reaction-product for the presence of sulphide by means of sodium nitroprusside. —A. S.

ORGANIC—QUANTITATIVE.

Dyestuffs: Quantitative Determination of some —. *Dyed Cotton Fabrics.* E. Knecht. *J. Soc. Dye and Colourists*, 1905, 21, 3—6.

DIRECT cotton (azo) dyestuffs can be accurately determined on the fibre by direct titration with titanous chloride (compare this *J.*, 1903, 825). Active chlorine removed from the fabric by boiling for about 5 minutes with hydrochloric acid (1:3), carbon dioxide passed into the solution, the titanous chloride solution added and heat applied until the colour has disappeared when the contents are cooled, and the excess of titanous chloride determined by titration with ferric alum solution, using potassium thiocyanate as indicator. The passage of the current of carbon dioxide is continued throughout the operation. Accurate results were obtained by this method with Benzopurpurin 4B, Chrysophenine Brilliant Yellow and Erika B, and it was found applicable to the determination of Methylene Blue the only basic dyestuff tried. In determining the amounts of dyestuff on cotton dyed in mixed shades, the remarkable selective action of titanous chloride was observed; thus, in greens obtained from Diamine St Blue and Chrysophenine, Chrysamine or Stilbene Yellow C, respectively, the yellow was always destroyed first leaving the pure blue on the fibre. —T. F. B.

Methylene Blue: Determination of —. E. Knecht. *J. Soc. Dyers and Colourists*, 1905, 21, 9.

ONE gram of Methylene Blue is dissolved in 250 c.c. of water, and 50 c.c. of this solution are warmed with a few drops of hydrochloric acid; a current of carbon dioxide is then passed through the solution and a standard solution of titanous chloride run in until the colour has just disappeared; the end point of the reaction is found to be quite sharp. On the assumption that 1 mol. of the dyestuff requires 2 atoms of hydrogen for reduction a sample of pure Methylene Blue was found by this method to contain 95—96 per cent. of dyestuff at 4.0 per cent. of water. The method described by Fell and Garuti (this *J.*, 1904, 1047) is considered inadequate for general use, since the differentiation between samples of nearly equal strength would necessitate exceedingly delicate manipulation and observation. —T. F. B.

Beeswax: Analysis of —. G. Buchner. *Chem.-Zeit.* 1905, 29, 32.

THE following method is recommended as giving

highest (and concordant) results in the determination of the saponification value of beeswax. After the determination of the acid value, the wax (5 grms.) is boiled for an hour over wire gauze with 3 c.c. of $N/2$ alcoholic potassium hydroxide solution in a flask connected with a Soxhlet's extractor and Vigreux's condenser. The continual concentration of the liquid in the flask leads to more complete saponification, and the maximum values are obtained after 1 hour with beeswax, whether pure or containing ceresin. If saponification be carried out in a flask with a long tube to act as condenser, maximum values are also obtained with beeswax after 1 hour, but samples containing ceresin require the boiling to be continued for several hours. The author confirms the value of Werder's proposal of amyl alcohol as the saponifying medium in the case of waxes of high melting point, e.g., carnauba wax and montan wax.

It is pointed out that abnormal values in beeswax may sometimes be due to alterations in its constituents. For instance, a beeswax of known purity gave the following values: acid value, 23.3; saponification value, 95.7; and ratio number 3.0. Here the ratio number is small, but the acid value appears to have been raised at the expense of the ester value. In the bleaching of beeswax, this change can be plainly observed.

			Acid Value.	Saponification Value.	"Ratio" Number.
Beeswax before bleaching	20.0	95.1	3.7
.. after	25.1	95.1	2.8

Ghedda Wax.—In the author's opinion, this Indian wax affords another example that such changes may occur naturally in beeswax. Thus, a sample gave the following results: acid value, 5.33; and saponification value, 95.68. Calculating from the normal ester value of beeswax (75) and adding the difference between this and the "ester value" found, to the acid value, gives results agreeing with the normal values for ordinary wax. The composition of a specimen of Ghedda wax calculated from the analytical values, the amount of melissyl alcohol (determined by Buisson's method of fusion with potassium hydroxide) and determination of hydrocarbons, was found to be as follows: stearic acid, 5.13; palmitic acid, 37.87; melissyl alcohol, 10.09; and hydrocarbons, 8.65 per cent.—C. A. M.

Rules for Testing Boiled Linseed —, issued by the Russian Minister of Marine. Chem.-Zeit., 1905, 29, 56.

COMMISSION appointed by the Russian Minister of Marine has reported that the following tests are to be applied to all boiled linseed oil delivered to that Department:—

I. APPEARANCE: (a) *Colour:* This may be light to dark brown. (b) *Transparency:* Complete transparency desired, but certain oils that are transparent at first, may become slightly turbid from the separation of traces of lead or manganese soaps, without depreciation of their value. **II. PRACTICAL TESTS:** (a) The varnish is read in a thin layer on glass and kept at 16—19° C. A dark varnish should not be sticky after, at most, 12 hours. A light varnish after 20 hours. The film should be completely and be brilliant and elastic. (b) The durability is determined by drying the film for 24 hours in an oven at 100° C. There should be no cracks and the film should yield shavings when scraped with a knife.

There should be but little darkening in shade when the white or chemically pure white lead are rubbed with the varnish. (d) Twenty-five parts of the varnish are mixed with 20 parts of zinc white and the mixture spread over a smooth slab of wood. The paint ought to dry within 8 to 9 hours. (e) The presence of fish oil is recognised by the unpleasant odour, which is more

perceptible when the oil is rubbed between the hands or warmed. **III. CHEMICAL TESTS:** (a) The specific gravity at 15° C. must not be less than 0.941. (b) Mineral, resin or turpentine oils are detected by saponifying the oil by boiling it under a reflux condenser with alcoholic potassium hydroxide, and diluting the soap with 2 to 3 parts of water. Pure boiled linseed oil furnishes a completely transparent solution. Resinous substances can also be identified by means of the polarimeter. In doubtful cases, the varnish is distilled with steam and the distillate examined for hydrocarbons. (c) Small amounts of colophony are admissible, but the acid value of the oil must not exceed 8. This value is determined by dissolving 10 grms. of the sample in 50 c.c. of warm neutralised alcohol and titrating the solution with $N/10$ alcoholic potassium hydroxide solution, with phenolphthalein as indicator. (d) The amount of ash must not exceed 0.75 per cent.—C. A. M.

Malt, Wort and Beer; Determination of the Ash of —, and the Proportion of Sulphuric Acid in the Ash. W. Windisch. Woch. f. Bran., 1905, 22, 17–18.

According to the standard German method for the determination of the sulphuric acid in the ash of brewery products, the ash is prepared for this purpose by incinerating the material in presence of a base, such as baryta or sodium carbonate. The author shows the great necessity for this precaution, since certain beer ashes which contained 16–18 per cent. of sulphuric anhydride when prepared in presence of sodium carbonate, contained only 1.76–3.25 per cent. when prepared by incineration without a base. Consequently the published analyses of ashes of such materials, which have been prepared in the latter way, are not correct, so far as the sulphuric acid is concerned. The difference is attributed partly to the volatilisation of organic sulphur, but mainly to the reduction of the sulphates to sulphides. It is shown that the primary phosphates of the ash decompose the sulphides produced, with the evolution of sulphuretted hydrogen. For this reason also, it is desirable that the determination of the ash itself should be made with the addition of a basic substance.—J. F. B.

Gluten in Wheat Flour; Determination of —. E. Fleurent. Comptes rend., 1905, 140, 99–101.

A WEIGHED quantity of the flour is made into a dough with a little water. The cake of dough is kneaded with water containing 0.1 gm. of chalk per litre, the water also containing sufficient carbon dioxide to hold the chalk in solution. The temperature of the water should be 16° C. Eleven minutes are required for the kneading and 2 minutes for a final washing, or 13 minutes in all. The gluten is then dried at 100–105° C. and weighed. The use of distilled water slightly diminishes the yield of gluten, as does also the substitution of calcium sulphate or chloride for the calcium bicarbonate. The presence of sodium chloride in the wash-water decreases the yield in a similar manner. Old, acid flour must be previously treated with sodium bicarbonate in order to obtain the correct quantity of gluten.—W. P. S.

Phenol; Determination of —. S. J. Lloyd. J. Amer. Chem. Soc., 1905, 27, 16–24.

OF the different workers who have devised methods for the determination of phenol based upon the reaction: $C_6H_5OH + 3Br_2 = C_6H_2Br_3OH + 3HBr$, Beckurts (this J., 1886, 516) recognised that some tribromophenol bromide, $C_6H_2Br_3OBr$, was formed, but assumed that it was quantitatively converted into tribromophenol by potassium iodide. The author finds, however, that the conversion of the tribromophenol bromide into tribromophenol by potassium iodide is not complete. The formation of tribromophenol bromide can be prevented by working in a strongly acid solution, and the following method is recommended:—The solution containing the phenol is treated in a stoppered flask with a volume of hydrochloric acid (sp. gr. 1.2) equal to about one-third or one-fourth of the combined volumes of the phenol solution and the hypobromite solution that will probably be required. A standardised solution of potassium hypobromite (9 c.c. of bromine dissolved in 2 litres of a solution containing

28 grms. of potassium hydroxide is then added, until the solution becomes permanently yellow, followed by a further quantity 10-20 per cent. of the amount previously added of the same solution, and an excess of potassium iodide solution (17 grms. per 100 c.c.). The solution is diluted, 10% of chloroform added, and the free iodine determined by titrating with a $\text{Na}_2\text{S}_2\text{O}_3$ solution of thiosulphate. It is estimated in this way, the phenol can be determined to within 1 or 2 parts per 1000 A.S.

XXIV. SCIENTIFIC & TECHNICAL NOTES.

Notes on the Action of Pyridine on Lactic Acid. — Annalen, 1901, 338, 71-101.

The most probable explanation yet given of the formation of a racemate is that, in solutions of different rotatory powers, the sugar exists in two inter-convertible "anomeric" forms, which readily pass over into each other, possibly with intermediate formation of the aldohydrin modification (see Levy, this J., 1903, 828). The hydrate theory of birotation has been disposed of by Behrend and Ritt (this J., 1904, 388), whose results were confirmed by E. F. Armstrong (this J., 1904, 388), and by Jungius and Lubert de Bruyn (Konink. Akad. wetensch. Amsterdam, 1904, 860). By acetyating galactose in pyridine solution under different conditions, the author demonstrates the existence of three isomeric pentaacetyl galactoses, and also the close connection between these compounds and the modifications of galactose having different rotatory powers. — F. H. P.

Prizes.

Cements: Investigations on Hydraulic —.

The Prussian Minister of public works, jointly with the Prussian ministers of war, agriculture, and trade and industry, the imperial secretary of the navy, and the German society of Portland cement manufacturers, issued a call for a prize competition of essays on the chemical processes which take place during the hardening of hydraulic cements. Prizes to the amount of 15,000 marks are offered, and the prospectus specifies that contributions must be submitted in the German language, each signed with a pseudonym, and the name of the author inclosed in a sealed envelope marked with the same pseudonym, which latter will be opened only in case the paper bearing such pseudonym receives a prize. Thus prepared, all papers for competition are to be addressed to the "Ministry of Public Works, No. 84, Wilhelm Strasse, Berlin," where they will be received until 3 p.m. December 31, 1903.

The papers will be submitted to a jury composed as follows: Prof. van Hoff, Berlin; Prof. Scheibbe, Wilmersdorf; Dr. Michaelis, Berlin; E. Cramer, editor of the *Thonindustrie Zeitung*, Berlin; Prof. W. Fresenius, Wiesbaden; Director F. Schott, Heidelberg; Dr. H. Passow, Hamburg, and officials of the royal testing station near Berlin.

The scope of the investigation is indicated by the following translation of the schedule which defines the questions to be solved:

Demonstration of the properties and of the hardening process of calcareous hydraulic cements, synthetically, analytically, microscopically, mineralogically (hardening in air, fresh water, and sea water).

(a) To prove whether silicic acid, alumina, and oxide of iron combine with lime as crystalloids in stable proportions, or as colloids in varying proportions.

(b) To prove whether double combinations result between silicic acid, alumina, and oxide of iron with lime, and in what manner these substances are engaged in the hardening process.

(c) Consideration of the swelling phenomenon which accompanies the hydraulic hardening.

(d) Consideration of the influence of the temperature and length of time of the burning process on the different kinds of hydraulic cements.

(e) Properties of puzzolana and its hardening with lime, beginning with silicic acid as the most active and prevailing puzzolant, alumina, oxide of iron, and manganese independently and in combination with silicic acid, either natural or artificial puzzolant.

The competitors may choose for the purpose of investigation any or all of the foregoing questions.

New Books

TECHNO-CHEMICAL ANALYSIS. By Dr. G. LUN. Authorised Translation by ALFRED I. CORN. Fifth Edition. John Wiley and Sons, New York. Chapman and Hall, Ltd., London. Price 4s. 6d.

SMALL 8vo volume, with table of contents, bibliography, 128 pages of subject matter with 16 illustrations, and alphabetical index of subjects. The subjects treat may be brought under the following classes:—I. Scope, techno-chemical analysis. II. General operations preceding Analysis. III. Technical Gas-Analysis. IV. Volumetry. V. Fuels and Heating. VI. Water. ORGANIC CHEMICAL MANUFACTURES. I. Sulphurous and Sulphuric Acids. II. Nitric Acid. III. Sulphates. Hydrochloric Acid. V. Soda. VI. Carbonated L. VII. Chlorine Industry. VIII. Potassium Salts. Clay and Cement Industry. X. Artificial Mannures. Gas and Ammonia Manufacture. APPENDUM I. Calcium Carbide. II. Coal-tar Industry. III. Mineral Oils. Oils and Fats; Soaps; Glycerin and Sugar. V. Alcohol Manufacture (Brandy, &c.). VI. Vinegar, Wine; Beer Brewing; Tanning Materials; Dyeing.

DER PYROGENE ZERFALL DES KAUTSCHUCKS. Aeltere u. Neuere Studien über die Produkte der trocknen Destillation des Kautschuks. Von Dr. RUDOLF HITMAR. Steinkopff und Springer, Dresden—A. Germany. Price M.1.

PAMPHLET of 38 pages, containing at the end details of literature on the subject, and also on closely associated subjects (Isoprene and Dipentene).

BULLETIN OF THE BUREAU OF STANDARDS. Department of Commerce and Labor; U.S. America. Vol. I, No. 8. W. STRATTON, Director. Issued November 1, 1902. Government Printing Office, Washington, U.S. America. 1901.

LARGE 8vo volume containing 124 pages of subject matter with illustrations. The subjects treated of in this volume are as follows:—I. Recombination of the United States Prototype Meter. II. Study of the Silver Voltameter. III. So-called International Electrical Units. IV. Speed of Mixed Gases. V. Secondary Spectra and the Conditions under which they may be Produced. VI. Some Non-Rectifying effects in Conducting Gases. VII. Fibres resembling Quartz in their Elastic Properties. VI. The Temperature of the Arc.

JAHRBUCH DER ELEKTROCHEMIE UND ANGEWANDTE PHYSIKALISCHE CHEMIE. Begründet und bis 1902 herausgegeben von Prof. Dr. W. NERNST und Prof. Dr. W. BÖRCHERS. Berichte über die Fortschritte des Jahres 1903. Unter Mitwirkung der Herren Dr. Askenasy; Prof. Dr. K. Elbs; Dr. F. Harms; J. Hey; Dr. H. Ley; Dr. J. Meyer; Dr. M. Mugden; Dr. O. Sackur. Herausgegeben von Dr. H. Danner. N. Jahrgang. Wilhelm Knapp's Verlag, Halle a. S. 1905. Price M.26.

LARGE 8vo volume, containing 837 pages of subject matter with 137 illustrations, 9 pages devoted to New Books of the year 1903, a list of Journals consulted in compiling the work, and alphabetical Indexes of subjects and names of authors, &c., to page 930. The work is divided into two sections, and is arranged as follows:

SCIENTIFIC SECTION. (i) General. (ii) Educational. (iii) Apparatus and Methods. (iv) Systematising the Chemical Substances. (v) Doctrine of Phases and Analysis. (vi) Laws of Mass Action, Hydrolysis, &c. (vii) Conductivity, &c. (viii) Chemical and Electrical Energy. (ix) Polarisation and Electrolysis, &c. **ALLIED ELECTROCHEMISTRY.** (i) Current-production. (ii) Inorganic Electrochemical Processes and Products. (iii) Carbides. (iv) Metals. (v) Organic Compounds. (vi) Electrolysis of Alkali Chlorides and Bleaching Apparatus. (vii) Electrical Furnaces. (viii) Galvanology and Allied Branches. (ix) Apparatus for the Electrochemical Technology.

MANUAL OF CHEMICAL ANALYSIS AS APPLIED TO THE ASSAY OF FUELS, ORES, METALS, ALLOYS, S.L.T.S., AND THEIR MINERAL PRODUCTS. By EUGENE PROST, D.Sc., translated from the original by J. Cruickshank Smith, J.Sc., &c. MacLaren and Sons, 37 and 38, Shoe Lane, London, E.C. D. van Nostrand Company, 23, Murray ad 27, Warren Streets, New York, U.S.A. 1901. Price 12s. 6d. nett., 13s. post free; 14s. to Colonies and abroad.

PRICE 8vo volume, containing prefaces, and 296 pages of subject matter with 44 illustrations. The subject matter is divided into three parts:—I. FUELS, WATERS, ORES, S.L.T.S. AND OTHER MINERAL INDUSTRIAL PRODUCTS. II. METALS, including Iron and Steel; Copper; Zinc; Lead; Antimony; Tin; Nickel; and Antimony. III. ALLOYS.

Trade Report.

I.—GENERAL.

CHEMICAL AND MINERAL TRADES IN AMERICA.

C. Schnatterbeck. Eng. and Mining J., Jan. 5, 1905.

Consumption in most lines in 1904 was unsatisfactory, prices low, impairing profits. Imported products from Great Britain and the Continent are feeling the expansion of domestic production; thus, imports of chlorate of ash have fallen off about 82 per cent.; caustic soda, 28 per cent.; bleaching powder 22 per cent.; and ash, 14 per cent. "Sal soda," however, showed an increase of 31 per cent. in imports as a result of the heavy consumption. Cement receipts have been 62 per cent. more than 1903, and domestic exports have increased 1 per cent. Imports of salt are 9 per cent. larger than 1903, while domestic exports show nearly three times as much increase. Raw materials, notably nitrate of soda, continued high in price.

Interesting developments during the year were the liquidation of an additional \$6,000,000 in 8 per cent. preferred stock to liquidate the loan made by the Virginia Chemical Company; payment of 6 per cent. dividend on the preferred shares of the American Agricultural Chemical Company; suspension of dividends by the General Chemical Company, because of a depression in business and serious loss by fire and flood; initial dividends of 5 per cent. on the \$25,000,000 preferred stock of the E. I. Du Pont de Nemours Company, and 2.5 per cent. on the \$9,000,000 common stock of the International Nitrocellulose Powder and Chemical Company, which has a substantial Government contract and is controlled by the wider trust; increase in capitalisation of the Pennsylvania Salt Manufacturing Company from \$3,000,000 to \$6,000,000, yielding 12 per cent. in dividends annually; purchase of additional salt lands at Delray, Michigan, by the Solvay Process Company; erection of new by-product ovens by the Smet-Solvay Company, one of the largest producers of gas-liquor sulphate of ammonia in the United States.

In heavy chemicals the feature has been bleaching powder, which, since the signing of the triangular agreement among the manufacturers in Great Britain, the Continent and America, has advanced, selling at \$1.20 to \$1.25 per 100 lb. for prime brands on contract delivery. No shipments from Great Britain to the United States

have fallen off about one-third in favour of the Continental makers. Total imports were approximately \$8,587,628 lb., as against \$13,285,240 lb. in 1903; showing a decrease of 21,697,612 pounds. Soda compounds have been steady, advancing for 1905 delivery. Caustic soda, of which imports were about 2,179,803 lb. or 790,983 lb. less than 1903, sold at \$1.90 to \$1.95 per 100 lb. for foreign, f. o. b. New York, while domestic high test brought \$1.75 to \$1.85 at works. Alkali imported to the extent of 18,907,915 lb., as against 21,859,305 lb. in 1903, moved at \$5 to \$2.50, per 100 lb. for foreign at New York, and 72.5 to 77.5 for domestic at works. Sal soda imports were 4,511,228 lb., against 3,451,005 lb. in 1903, while selling prices were 67.5c. per 100 lb. for foreign at New York, and 60c. for ordinary domestic at works. Chlorate of potash, of which the imports fell to 85,638 lb.—the smallest quantity on record—suffered a decline in price to 7c. to 8.75c. per lb. for foreign at New York, and 6.5 to 8.75c. for domestic.

Owing to competition, cyanide sold at 17 to 20c. per lb. at New York. Small exports were made, principally to Mexico and Canada, at rather low prices compared to domestic deliveries. With an increased demand from the Transvaal gold mines, the European situation has improved materially.

Copper sulphate exports have increased, amounting to 25,650,000 lb., indicating an advance in price from \$4.90 to \$5.40 per 100 lb. for domestic deliveries, and from \$3.77 to \$4.81 for export. Small quantities of British makes have been imported, paying a duty of 0.5 per lb., and selling at about domestic prices.

Acids were firm in price, because of the strength in raw materials. Oxalic acid, imported to the amount of about 5,500,000 lb. per annum, sold at \$5 to \$5.50 per 100 lb. at New York—a price that affords little profit. Nitric acid, manufactured on a large scale in the United States, has been marketed at \$4.50 to \$5 per 100 lb. for 26° in carboys, f. o. b. New York; \$4.75 to \$5.25 for 28°; \$5 to \$5.50 for 40°, and \$5.375 to \$5.75 for 42°, the higher price ruling at the close of the year for 1905 shipments. Hydrochloric acid ruled steady at \$1.50 per 100 lb. for 18°; \$1.60 for 20°, and \$1.75 for 22°, f. o. b. New York.

Copperas shows an increased consumption in the purification of water, preparation of pigments, &c. Being controlled by an understanding among makers, the price has been unchanged from 47.5c. per 100 lb. in bulk, and 52c. in barrels, f. o. b. New York.

Alum was in good demand, and contracts for 1905 have been booked at unchanged prices, namely, \$1.75 to \$1.80 per 100 lb. for lump, \$1.80 to \$1.85 for ground, and 90c. for paper stock. Tin crystals were advanced from 18c. to 22c. per lb. in barrels, suggesting that competition among makers has been quieted.

The barytes trade has seen keen competition, partly the result of expansion in the domestic production, oversupply of the poorer grades, and a scarcity of prime white. American crude No. 1, sold at \$9.75 per short ton; No. 2 at \$8, and No. 3 at \$7; snow-white at \$15 to \$16; while foreign gray brought \$13.50; snow-white \$17.25 to \$18.75.

Asbestos for fire-proofing purposes has been in active demand this year, and besides meeting the domestic consumption, the United States has made exports to Europe at remunerative prices. As the crude mineral is largely under contract to a few manufacturers, market prices have ruled steady.

Asphalt, of which the United States consumes annually about one-third of the world's supply, shows a decrease of over 25 per cent. as a result chiefly of competition with other paving materials. Imports were approximately 123,500 tons, mostly from Trinidad, as trade with Venezuela has been interrupted by the litigation between the Castro Government and the American Company operating the Sucre deposits.

III.—TAR PRODUCTS, PETROLEUM, Etc.

PITCH; ARCHANGEL —: U.S. CUSTOMS DECISION.

Nov. 22, 1904.

Merchandise invoiced as Archangel pitch, but which

on analysis was shown not to be a wood tar pitch but a preparation from the residues of the distillation of fatty acid compounds, was held to be dutiable at 20 per cent. *ad valorem*, under section 6, as a "manufactured article unenumerated." As the importer presented no evidence to support his claim for free entry as a "wood pitch or tar," under paragraph 678, it was overruled.—R. W. M.

V.—TEXTILES, YARNS, AND FIBRES.

ALIZARIN ASSISTANT: U.S. CUSTOMS DECISION.

Nov. 15, 1904.

Merchandise invoiced as lubricating oil, but consisting of a sulfonated saponification of resin and other oils and containing no castor oil, was decided to be dutiable at 30 per cent. *ad valorem*, under paragraph 32 of the present tariff, as "alizarin assistant not otherwise provided for"—R. W. M.

VII.—ACIDS, ALKALIS, AND SALTS.

SULPHUR AND PYRITES IN THE UNITED STATES.

C. C. Schnatterbeck. *Eng. and Mining J.*, Jan. 5, 1905.

The development of the Louisiana sulphur industry has resulted in a reduction in the imports of brimstone, alarming the Sicilian combination, which, by exporting about one-third of its output to America at an advance of 3 dols. to 7 dols. per ton, has in eight years, increased its profits 221 per cent. Sulphur recovered from pyrites, produced largely in Virginia, and imported from Spain and Canada, duty free, is used chiefly in the manufacture of sulphuric acid, while the brimstone from domestic mines and imported from Sicily and Japan, also free of duty, is consumed by paper mills. The consumption of sulphur as pyrites and brimstone in this country in the last two years is estimated as below, in long tons:

	1903.	1904.
Sulphur, domestic	34,396	191,250
Net imports	186,237	129,454
	220,633	320,704
Pyrites, sulphur, domestic	87,730	79,976
Net imports	200,215	196,048
	287,945	276,024
Total consumption	508,578	596,728

Apparently brimstone furnished 53.8 per cent. of the total consumption, and pyrites 46.2 per cent., which compares well with 1896—the first year of the Sicilian combination—when the ratio of consumption was 50.7 per cent. for brimstone, and 49.3 per cent. for pyrites sulphur.

Small lots of Louisiana sulphur have been exported to Europe, and sold at comparatively higher prices than domestic deliveries. It is said that, owing to the low cost of production and purity of this sulphur, it can be sold in Italy at the Sicilian's cost of mining and preparing for market. Approximately 106,294 tons of Sicilian brimstone have been exported to the United States in 1904, as against 155,996 tons in 1903, and 168,919 tons in 1902. Some Japanese sulphur arrived at San Francisco for gunpowder and acid factories, notwithstanding the war with Russia.

The industry in Sicily has suffered from heavy rains during the fusion season, from intermittent labour troubles, and a smaller demand from America and Great Britain, though exports to vine countries, notably France and Italy, have increased. Fearing the growth of the American industry, the Chambers of Commerce at Girgenti and Caltanissetta have asked a government investigation, while the local press in Italy proposes to raise a fund of 10,000 dols. by public subscription, as a premium to the inventor of new uses for brimstone. Meantime the Anglo-Sicilian Company, controlling about 80 per cent. of the sulphur stocks at seaports, amounting to over 365,000 tons

—nearly a year's export—is promising the mine-owners more money if they will renew the agreement which expires in June, 1906, for another 10 years.

Trade in pyrites has been rather unfavourable as a result of keen competition and low prices in the face of decreased consumption. New deposits are being opened in Alabama. Calculated on the sulphur content, and allowing for expense of burning, consumers of pyrites are paying from 25 to 50 per cent. less than is charged for brimstone.

Sulphuric acid, the manufacture of which in the United States is controlled by a few concerns who are on friendly terms, has held firm 50 in bulk, selling at 13.50 dols. at 11.50 dols. per ton; 60 at 18 dols. to 20 dols., and at 21 dols. to 23 dols., f. o. b. New York. Acid in carload lots is worth from 3 dols. to 6 dols. per ton more. Manufacturing costs have been reduced by improvements, and much attention is now being given to contact process, while one American patent has been issued for an electrolytic method.

BROMINE IN THE UNITED STATES.

Eng. and Mining J., Jan. 5, 1905.

A record production for the United States was reported in 1904, amounting to 897,100 lb., which includes the bromine contained in bromides, all of which was made in Michigan. As compared with the 597,000 lb. output of 1903, this shows an increase of over 50 per cent. In the order of their importance, the producing States are Michigan, Ohio, Pennsylvania and West Virginia.

The market for bromine and bromides has been good during the past year, and at times the urgent demand advanced prices. Prices at New York were 48 cents per lb. for bromine in bulk, and 30 cents for potassium bromide.

FLUORSPAR IN THE UNITED STATES.

Eng. and Mining J., Jan. 5, 1905.

A notable expansion in the consumption of fluor spar in the United States is taking place, from which higher prices have resulted. Foundries find it advantageous to use more fluorspar for thinning their slag, thereby strengthening and purifying their castings, especially when much scrap is used. It is also used in making open-hearth steel, with excellent results. A further advance in price is expected during the ensuing year, as a result of the increased demand from cupolas. At present, Kentucky gravel fluorspar, unwashed, containing about 15 per cent. silica and 73 per cent. calcium fluoride is quoted at 3.50 dols. per ton, f. o. b. at shipping point, carrying 80 per cent. fluoride, at 4 dols.; 90 per cent. at 5 dols.; 95 per cent., at 6.50 dols.; 98 per cent., at 7.70 dols. per ton. Ground mineral, 99 per cent. fluoride, is worth 12 dols. per ton, and the pure mineral for acid making 15 dols. Imported fluorspar is quoted at New York at 8—10 dols. per ton for lump, and 11.50—13.50 dols. or ground.

NITRATE OF SODA IN THE UNITED STATES.

Eng. and Mining J., Jan. 5, 1905.

The American consumption in 1904, principally in the blasting powder and fertiliser manufacturing industry, was the largest on record—275,000 long tons—notwithstanding the high prices of 45.26 dols. to 53.20 dols. per ton. The European deliveries, mostly to sugar-refining countries, were approximately 1,105,000 tons, being less than 1903 by reason of business depression in the distributing markets. About 28,000 tons were consumed by the powder factories of the nitrate companies in Chile, and by agriculturists in neighbouring countries.

PHOSPHATE INDUSTRY OF THE UNITED STATES.

Eng. and Mining J., Jan. 5, 1905.

In 1904 the production of phosphates in the United States, principally in Florida, Tennessee and South Carolina, amounted to approximately 1,782,503 long tons.

valued at 5,703,582 dols. This is an increase compared with 1903 of 212,275 tons in quantity, and 709,670 dols. in value. Exports in 1904, chiefly to Germany, France, Italy and Great Britain, totalled about 880,000 tons, as against 785,259 tons in 1903, showing an increase of 94,741 tons, or 12 per cent. The ocean freight was 2.64 dols. to 72 dols., equivalent to from one-third to one-half of the i. f. prices paid for the phosphates, which were 9.84 dols. to 12.09 dols. for Florida high-grade rock; 6.39 dols. to 40 dols. for land pebble; 9.54 dols. to 11.40 dols. for Tennessee rock; 5.61 dols. to 6.88 dols. for South Carolina rock. In competition with the American phosphates were exports of 775,000 tons from Africa, paying an ocean freight of 1.44 dols. to 2.22 dols., and selling in Europe at dols. to 7.60 dols. for Algerian, and 5.75 dols. to 6.60 dols. for Tunis rock. There were also sent to Europe in 1904 some 125,000 tons of high-grade phosphate from Christmas Island and Ocean islands, paying a freight of about 6.48 dols., and marketed at 11.75 dols. to 14.45 dols. per ton, delivered. In all, Europe imported from the countries named a total of 1,780,000 tons, valued at approximately 1,375,683 dols., of which 5,105,650 dols. or over 50 per cent. represented cost of freight.

III.—GLASS, POTTERY, AND EARTHENWARE.

CARBORUNDUM: U.S. CUSTOMS DECISION.

Nov. 14, 1904.

Silicon carbide or carborundum was assessed for duty at 1 cent. per pound as "manufactured emery," under paragraph 419 of the present tariff. In the absence of testimony as to the character and uses of the article, the court held that it was dutiable at 20 per cent. *ad valorem* under section 6, as a "manufactured article enumerated," as overruled, and the assessment of duty affirmed.

—R. W. M.

X.—METALLURGY.

TIN PRODUCTION IN 1904.

Eng. and Mining J., Jan. 12, 1905.

The production of tin in 1904 is estimated as follows, in long tons of 2240 lb. :—

	1904.	1903.
	Tons.	Tons.
Straits	58,657	55,365
Banka and Billiton	14,638	18,720
Australia	5,082	4,377
Malaya	9,260	9,790
England	4,282	4,300
Germany and Austria	100	100
Miscellaneous	125	100
Total	92,084	92,752

The decrease in 1904 was thus 0.7 per cent., notwithstanding the considerable increase in the Straits output, and the smaller, though proportionately large, gain in Australia. This was more than offset by the reduction in the Banka and Billiton sales and output, while the Singapore mines produced no tin during the year.

Outside of this tin, which is included in the table above, there is a production in China which is not given, because it is entirely impossible to ascertain its actual amount. Estimates vary from 10,000 to 20,000 tons yearly, but the latter figure is probably too high. Nearly all this tin, whatever its amount may be, is consumed in China itself, though occasionally some parcels of Yunnan tin appear on the London market. Allowing for this production, it appears that the world's supply of the metal is a little over 100,000 tons yearly.

The German official returns show a production of about 5000 tons of tin yearly in that country, but this is almost entirely from foreign ores. There are also some 250 tons of pig tin produced yearly in Germany from tin scrap, and a small quantity is made in the same way in the United States. This, however, is not new metal.

The Metallgesellschaft, of Frankfurt, gives the consumption of tin during 1904 approximately as follows:—

	Tons.
United States	35,500
Great Britain	16,548
Germany	14,832
France, Italy, Spain, Russia	17,920
Eastern Europe and South America	4,200
Eastern Asia	3,300
Total consumption	94,755

Thus the consumption, as reported in 1904, exceeded the output by 2681 tons. This apparent excess of consumption is equal approximately to the increase in public stocks, which was 2973 tons. These public stocks include the quantities known to be in store in Great Britain, Holland and the United States, together with the tin known to be afloat, or in transit to those points from producing countries.

COPPER, LEAD, ZINC, TIN, NICKEL AND ALUMINIUM: PRODUCTION AND MARKET POSITION OF —, DURING THE LAST TEN YEARS.

F. Krull. *Zeits. angew. Chem.*, 1905, 18, 84—92.

Statistics relating to the production and consumption of the metals enumerated above, during the past decade, are given in a series of tables, curves and diagrams, which are based upon the official publications of the various countries concerned and of large business houses.

Copper.—The world's production increased from 330,000 tons (1 ton=1000 kilos) in 1894 to 500,000 tons in 1903; the consumption, from 225,000 tons to 372,000 tons in the same period; whilst the average London price for the year rose from 39.7*l.* per ton in 1894 to 72.5*l.* in 1899 and 1900, falling to 51.75*l.* in 1902 and rising to 57.25*l.* in 1903. North America produced more copper than all other countries put together, the output rising from 162,355 tons in 1899, to 303,427 tons in 1903; the Montana mines were the chief contributors. Spain and Portugal together produced 55,042 tons in 1899, the output falling to 50,535 tons in 1903, the Rio Tinto mines being the main sources.

Lead.—The world's production increased from 622,000 tons in 1894 to 880,000 tons in 1903; the consumption, from 630,000 tons to 879,000 tons in the same period; whilst the average London price for the year, after rising steadily from 9.35*l.* per ton in 1894 to 16.4*l.* in 1900, fell to 11.05*l.* in 1902 and 11.55*l.* in 1903. The output from the United States rose from 129,300 tons in 1900 to 262,200 tons in 1903; that from Spain fell from 180,500 tons in 1898 to 163,400 tons in 1903. The consumption in the United States rose from 173,413 tons in 1894 to 284,466 tons in 1903; in England, from 161,847 tons to 232,317 tons; and in Germany, from 100,678 tons to 167,516 tons, in the same period; whilst that in France receded from 86,160 tons to 80,003 tons.

Zinc.—The world's production increased from 381,000 tons in 1894 to 571,000 tons in 1903; the consumption, from 384,000 tons to 578,000 tons in the same period; whilst the average London price for the year fluctuated between 10.35*l.* (in 1898) and 24.5*l.* (in 1900) per ton, the price in 1903 being 20.65*l.* Germany and America were the principal producers, and also the principal consumers.

Tin.—The world's output, 74,800 tons in 1894 fell to 70,400 tons in 1898, and thereafter rose steadily to 91,000 in 1903. The consumption rose somewhat irregularly from 62,100 tons in 1894 to 86,200 tons in 1903; whilst the average London price for the year fluctuated between 58*l.* (in 1899) and 131.5*l.* (in 1900), the price in 1903 being 125.3*l.* per ton. North America, Germany and Great Britain were the principal consumers.

Nickel.—The world's production rose from 1829 tons in 1889 to 9850 tons in 1903, about one-half being obtained from New Caledonia minerals and the balance mainly from the United States and Canada. The price has varied as follows:—1889, 4.5 marks per kilo; 1901, 2.9—3.2 marks; 1902, 2.9—3.5 marks; 1903, 3—3.75 marks.

Aluminium.—The production of aluminium rose from 4034 tons in 1898 to 7810 tons in 1900, and has since only slowly increased to 8252 tons in 1903, the limit to its uses

having apparently been reached. North America, Germany and France were the principal producers. The bauxite required in its manufacture is obtained chiefly from the south coast of France. The price of alumina, which in 1886 was about 100 marks per cwt., fell to 22½ marks in 1900, and is now about 25 marks per cwt. H. B.

MINERAL AND METAL PRODUCTION OF THE UNITED STATES DURING 1904.

Eng. and Mining J., Jan. 5, 1905.

The subjoined table gives the estimated mineral and metal production of the United States during 1904, the figures for 1903 being added for comparison:—

		1903.			1904.		
	Customary Measure.	Value.		Quantity.	Value.		
		Quantity.			Total.	Per Unit.	
Non-metallic:							
Arsenic, white	Sh. tons.	611	\$35,028	\$57.33	498	\$29,504	\$59.25
Barytes	do.	50,307	152,150	3.02	22,502	74,736	3.32
Bauxite	L. tons.	48,087	171,306	3.56	48,966	189,325	3.87
Bromine	Lb.	597,000	170,140	.29	897,100	313,985	.35
Carborundum	Lb.	4,760,000	476,000	.10	7,000,000	700,000	.10
Cement, natural hydraulic	Barrel (a)	7,030,271	3,675,520	.52	5,600,000	2,500,000	.50
Cement, portland	Barrel (b)	22,342,973	27,713,319	1.24	22,000,000	20,900,000	.95

(a) Barrel of 300 lb. (b) Barrel of 350 lb. (c) Includes cannel. (d) Includes a small amount made from metallic copper. (e) Existing only as a constituent (20% of hard lead. (f) Bismuth contents of ore mined, but not smelted, in the United States. (g) Average value of Lake copper at New York, less 0.25 c. per pound. (h) Average price at New York of Lake and electrolytic copper. (i) Flask of 75 lb. (j) Includes only that marketed as copperas.

PLATINUM IN THE UNITED STATES.

Eng. and Mining J., Jan. 5, 1905.

The production of platinum did not show an increase in 1904, although the demand for it continues very strong. As in previous years, fully nine-tenths of the production of this valuable metal were supplied by Russia, chiefly from placer workings in the Ural region. In 1903 the reported output in Russia was 204,892 troy oz. Some increase was made in that year, chiefly due to the introduction of dredges in the valley of the river Iss, where the most productive placers are found. In 1904 the production was curtailed on account of the war with Japan and the drafting of many of the Ural workers into the army.

Outside of Russia, the principal part of the supply comes from placer workings in Columbia, in South America. A small quantity is obtained in British Columbia, and other small amounts in Wyoming, Oregon and California. The California metal is obtained at the San Francisco Mint, in parting and refining gold, which comes from certain localities in that State. Some platinum and palladium, also recovered at the Orford Copper Company's works, at Constable Hook, N.J., in refining nickel matte from the Sudbury district in Ontario. The quantity of the domestic supply, however, is not sufficient to affect the market seriously, and the principal part of the metal used in America is imported from Russia. Most of it arrives in crude form, and is refined at the works in Newark, N.J.

and in New York. For the 11 months ending November 30, these imports are reported at 6,596 lb., which compares with 7,607 lb. in 1903, and 6,467 lb. in 1902.

Prices of platinum in the United States were very strong throughout the year, as supplies were not abundant, and the consumption in the electrical and chemical industries is generally increasing. The quotation for ingot metal, New York advanced from 18.50 dols. per oz. to 19.50 dols. at the close of the year.

MERCURY PRODUCTION OF THE UNITED STATES.

Eng. and Mining J., Jan. 5, 1905.

The production of quicksilver in the United States

the month of December, 1901, estimated, was as follows, in flasks of 76.5 lb. each:—

	1903.	1904.
Quicksilver	32,094	37,295
As	5,929	5,336
Total	37,123	42,631

Production was reported from the Black Butte mine in Oregon. Almost the entire increase came from the mines in Brewster County, in Texas, where development still continues encouraging, and where several new discoveries have been made.

The California producers last year decided to reduce the standard content of a flask of quicksilver from 76.5 to 75 lb. There has been a general compliance with the new standard. Texas producers, however, still report their output in flasks of 76.5 lb.

Exports of quicksilver for the eleven months ending December 30 were 1,280,298 lb. in 1903, and 1,479,298 lb. in 1904; an increase of 199,000 lb., or 15.5 per cent.

BISMUTH IN THE UNITED STATES.

Eng. and Mining J., Jan. 5, 1905.

In 1904 the United States re-entered the list of producers, producing 61 short tons of bismuth ore, as compared with 37.5 tons in 1902, and 318.6 tons in 1901. The total output, analysing from 7.5 to 15 per cent. metallic bismuth, with some gold and silver, came from Leadville, Colorado, and from a new mine near Banning, California. A new discovery has been made 40 miles west of Tonopah, Nevada, where the ore occurs as bismuthinite and as chlorite of bismuth, assaying 4.48 to 4.83 per cent. bismuth, 7 to 80 oz. silver, with a trace of gold. A small production is reported annually in Saxony, Germany, Australia and other countries. The war in the East stimulated demand for bismuth subnitrate and similar compounds for medicinal and surgical purposes. The United States imports annually about 200,000 lb. of metal, and a small quantity of bismuth salts in pharmaceutical compounds.

CUBA; MINING INDUSTRY OF —.

U.S. Cons. Rep. No. 2149, Jan. 5, 1905.

The output of the five Cuban asphalt mines in operation during 1904 was about 13,500 tons, valued at \$145,800. The three copper mines produced an output valued at \$900,000. Iron mines, of which twelve were worked, produced 729,336 tons, value \$29,330. The production of the three manganese mines amounted to 32,628 tons, valued at \$32,600. One naphtha mine was worked, and produced 60 tons during last year. The total mineral production was valued at \$289,200.

TIN DROSS: U.S. CUSTOMS DECISION.

Nov. 14, 1904.

Tin ashes were held to be free of duty, under paragraph 3 of the present tariff. The assessment of duty at 10 per cent. *ad valorem*, as "waste," under paragraph 463, is overruled.—R. W. M.

XIII. A.—PIGMENTS, PAINTS, Etc.

PAINT; DRY COPPER — : U.S. CUSTOMS DECISION.

Nov. 9, 1904.

It was decided that metallic copper in the form of powder, to some extent oxidised, and designed for use in the manufacture of copper paint, was dutiable at 10 per cent. *ad valorem*, as a "crude pigment," under paragraph 53 of the present tariff. The assessment of duty at 45 per cent. *ad valorem*, as a "manufacture of metal," under paragraph 193, was overruled.—R. W. M.

XIII. B.—RESINS, VARNISHES, Etc.

BALATA INDUSTRY OF BRITISH GUIANA.

Board of Trade J., Jan. 19, 1905.

The report for 1903-4 on British Guiana, prepared by the Assistant Government Secretary, states that in 1902-3 the balata industry was particularly successful, and in 1903-4 the amount of the gum obtained, 539,198 lb., was only 1,302 lbs. less. There has been a certain amount of prospecting for other varieties of rubber, and on one or two estates on the sea coast experimental planting has been done. In the new Crown Lands Regulations, which came into force in October last, opportunity was taken to provide more stringent and effective measures for the protection of the balata-producing forests.

RESINATE OF MANGANESE: U.S. CUSTOMS DECISION.

Nov. 22, 1904.

Resinate of manganese, consisting of resin soap, caustic soda and manganese sulphate, was held to be dutiable at 25 per cent. *ad valorem*, as a "chemical compound." The claim of the importer that it was dutiable at 1 cent per pound and 10 per cent. *ad valorem*, as a "gum advanced in value" was overruled.—R. W. M.

GUM SANDARAC IMITATION: U.S. CUSTOMS DECISION.

Nov. 18, 1904.

Merchandise invoiced as gum sandarac imitation was assessed for duty at 25 per cent. *ad valorem*, as a "chemical compound," under paragraph 5 of the present tariff. Analysis showed it to be a preparation of resin acids and not sandarac. The claims of the importers that it was dutiable at 1 cent per pound and 10 per cent. *ad valorem*, as a "gum advanced in value," under paragraph 20, or at 20 per cent. *ad valorem*, under section 6, as a "manufactured article unenumerated," were accordingly overruled.—R. W. M.

XIV.—TANNING; LEATHER; GLUE, Etc.

LENTISCUM: U.S. CUSTOMS DECISION.

The United States Circuit Court decided that the powdered leaves of *pistacia lentiscus* are free of duty as a "crude article used in dyeing or tanning," under paragraph 482 of the present tariff. This decision reverses the Board of General Appraisers, who had held the article to be dutiable at 1 cent per lb. and 10 per cent. *ad valorem* as a "drug, advanced in value," under paragraph 20, the Court holding that it was not a drug.—R. W. M.

BONE SIZE: U.S. CUSTOMS DECISION.

Nov. 9, 1904.

Following a decision of the United States Circuit Court, the Board of General Appraisers held that bone size is dutiable at 20 per cent. *ad valorem* under Section 6 of the present tariff, as a "manufactured article unenumerated." —R. W. M.

XVIII. C.—DISINFECTANTS.

SHEEP DIP: U.S. CUSTOMS DECISION.

Nov. 22, 1904.

Following a decision of the United States Circuit Court, the Board of General Appraisers held that an alkaline preparation of mineral oil and coal tar distillates containing pyridine bases and resin compounds, is dutiable at 25 per cent. *ad valorem* under paragraph 3 as a "chemical compound." Since the above compound can be used for other purposes than as a sheep dip, the claim for free entry under paragraph 657 was overruled.—R. W. M.

XX.—FINE CHEMICALS, Etc.

ETHYL CHLORIDE: U.S. CUSTOMS DECISION.

Nov. 22, 1904.

Ethyl chloride was held to be dutiable at 1 dol. per lb.

under paragraph 21 of the present tariff; the claim of the importer that it was dutiable at 25 per cent *ad valorem* under paragraph 3, as a "chemical compound" was rejected. R. W. M.

CIGARIN, AND CIGERINE. U.S. CUSTOMS DECISION. No. 25, 1904

The above-named articles were assessed for duty at 25 per cent *ad valorem* as "alcoholic liquors" under paragraph 2 of the present tariff act. The General Appraisers held, however, that they were dutiable at 55 cents per lb. or at not more than 50 per cent *ad valorem*, as "medicinal preparations containing alcohol and in the preparation of which sugar was used" under paragraph 67. R. W. M.

SULPHUR ETHER AND CELLULOSE FOR THE MANUFACTURE OF PHOTOGRAPHIC PAPER: FREE ADMISSION UNDER THE NETHERLANDS.

Indust. Trade J., Jan. 19, 1905.

A Dutch "Staatscourant" for the 7th January, contains the text of a Royal Decree exempting from import duty, subject to certain conditions, sulphuric ether and sulphuric acid in the manufacture of photographic paper.

Patent List.

N.B.—In these lists, [A.] means "Application for Patent," and [C.S.] "Complete Specification Accepted."

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journal, in which acceptance of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

 .. 6600 (1904). Cleminson Electric Light Attachment, Ltd., and King. Cement for use in electric lamps and for other purposes. Jan. 25.
 .. 27,857 (1904). Gerster, Freund, Freund and Imre. Manufacture of bricks from magnesite. Feb. 1.

X.—METALLURGY.

- [A.] 411. Gayley. Method of smelting ore. [U.S. A.] Oct. 25, 1904.* Jan. 9.
 .. 605. Bennett, Rodda and Rule. Method of separating bodies capable of being magnetised from others with which they are associated. Jan. 12.
 .. 690. Dawes. Separating gold or other metallic substances from fluids holding same in suspension. Jan. 13.
 .. 775. Delporte. Manufacture of steel.* Jan. 13.
 .. 792. Buttenshaw. Manufacture of bronze. Jan. 13.
 .. 961. Dekker. Method and apparatus for treatment of metallic compounds of sulphur, arsenic and antimony. [Fr. Appl., Aug. 1904.]* Jan. 17.
 .. 962. Haddan (Dekker). Process and apparatus for the treatment of sulphurous, antimonious and arsenious minerals.* Jan. 17.
 .. 969. Harrison. Cupolas for melting blast furnace slag. Jan. 18.
 .. 1169. Sium and Sellers. Magnetic separation. Jan. 21.
 .. 1211. Haslam. *See under I.*
 .. 1308. Jenkins. Magnetic ore separators. Jan. 18.
 .. 1356. Stanbridge. Method of hardening arm plates, projectiles, and other articles. Jan. 18.
 .. 1363. Holdsworth. Manufacture of marketable zinc products from zinc ore. Jan. 24.
 .. 1599. Goldschmidt. Method of and apparatus for treating tinned sheet iron for facilitating removal of the tin.
 .. 1697. Wynne. Machine for the concentration of ores or other substances of different specific gravities. Jan. 28.
 [C.S.] 1556 (1904). Malzac. Process for treating silicated ores (simple or complex) of nickel. Jan. 18.
 .. 4793 (1904). Wolf. Separation of metals from their ores. Feb. 1.
 .. 5041 (1904). Moore and Heskett. Apparatus for treating ferruginous ore for the manufacture of iron and steel therefrom. Feb. 1.
 .. 7658 (1904). Kunicke. Precipitating boxes for gold or other metal bearing solutions. Jan. 18.
 .. 19,142 (1904). Swyny and Plucknett. Process for the extraction of normally buoyant mineral particles from slimes, tailings and like metalliferous materials. Jan. 25.
 .. 23,906 (1904). Schwarz. Process for extracting metalliferous particles from ore and apparatus therefor. Feb. 1.
 .. 24,175 (1904). De Dion and Bonton. Manufacture of nickel steel. Jan. 18.
 .. 24,585 (1904). Blenkinsop. Treatment of copper ore. Feb. 1.
 .. 25,948 (1904). Soc. Electro-Métallurgique Française. Manufacture of steel. Feb. 1.
 .. 27,073 (1904). Wedge. Furnaces for roasting and smelting and analogous uses. Jan. 18.
 .. 27,865 (1904). Blackmore. Process of reducing aluminium and other metals. Feb. 1.
 .. 27,894 (1904). Vandevelde. Manufacture of steel. Feb. 1.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

- [A.] 521. Meusnier and Mounier. Secondary battery. Jan. 10.
 .. 778. Bloxam (Polzeniusz and Goldschmidt). Manufacture of accumulator plates. Jan. 14.

- A.] 839. Boulton (Smith). Electric storage battery negative pole plates.* Jan. 16.
 „ 1015. Galanti and Barrett. Electric accumulators. Jan. 18.
 „ 1017. Larsen. Apparatus for the electrolytic treatment of gases. Jan. 18.
 „ 1200. Scammell and Muskett. *See under IX.*
 „ 1360. Cramp. Apparatus for producing electric arcs, sparks, or flames for bleaching or sterilising purposes. Jan. 24.
 „ 1406. Roselle. Manufacture of plates for secondary electric batteries. Jan. 24.
 „ 1407. Roselle. Process of and apparatus for the manufacture of plates for secondary electric batteries. Jan. 24.
 S.] 5688 (1904). Johnson (Badische Anilin und Soda Fabrik). Apparatus for producing reactions in gases by means of electricity. Jan. 18.
 „ 6402 (1904). British Thomson-Houston Co., Ltd. (General Electric Co.). Electric insulating compositions. Jan. 25.
 „ 6600 (1904). Cleminson Electric Lamp Attachment, Ltd., and King. *See under IX.*
 „ 6792 (1904). Leitner. Method of preliminary treatment for electric accumulators plates. Feb. 1.
 „ 7056 (1904). Ashcroft. Production of metals of the alkali group by electrolysis. Jan. 18.
 „ 7061 (1904). Leeds Cooper Works, Ltd., and Jobling. Electro-depositing apparatus. Feb. 1.
 „ 25,095¹ (1904). Jungner. Electric accumulators. Jan. 18.
 „ 26,949 (1904). Mills (Edison). Continuous apparatus for nickel plating. Jan. 18.

(I).—FATTY OILS, FATS, WAXES, AND SOAP.

- A.] 1040. Silcock, Silcock and Stevenson. Extracting oil from seeds and the like. Jan. 19.
 „ 1292. Roussy de Sales. Process of manufacturing soap. [Fr. Appl. March 24, 1904.]* Jan. 23.
 „ 1572. Hemptinne. Process for converting oleic acid into stearic acid and like compounds. [Appl. in Belgium, March 19, 1904.]* Jan. 26.
 „ 1655. Bloom. Process of preparing oil for edible and other purposes and preparations embodying such and for the products of such processes.* Jan. 27.
 S.] 10,350 (1904). Klopfer. Process for producing soap. Feb. 1.
 „ 26,192 (1904). Di Salasao and Rovere. Process for reducing the density of mineral and vegetable oils. Feb. 1.

III.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

(A).—PIGMENTS, PAINTS.

- S.S.] 6217 (1904). Abel (Act.-Ges. f. Anilinfabr.). Manufacture of colour lakes from sulphur dyestuffs. Jan. 18.

(C).—INDIA-RUBBER.

- S.S.] 27,722 (1904). Ephraim. *See under XVI.*
 „ 28,051 (1904). Marx. Production of caoutchouc. Jan. 25.

IV.—TANNING; LEATHER, GLUE, SIZE, Etc.

- [A.] 1150. Bernstein. *See under XVIII. A.*
 „ 1158. Nicholas. Preparation for softening and preparing leather for the manufacture of gloves. Jan. 20.

- [A.] 1236. Kunick. Process for making casein and albumen more soluble. Jan. 23.
 „ 1371. Greenwood. Manufacture of agglutinant material. Jan. 23.
 [C.S.] 22,156 (1903). Payne. Preparation and use of tanning extracts. Jan. 25.
 „ 1477 (1904). Schneider. Manufacture of casein and gelatine. Jan. 25.

XV.—MANURES, Etc.

- [C.S.] 6101 (1904). Crane, Taylor and Williams. Manufacture of fertilisers. Jan. 18.
 „ 13,661 (1904). Hammerschlag. Manufacture of artificial manure or fertilisers. Jan. 18.

XVI.—SUGAR, STARCH, GUM, Etc.

- [A.] 1509. Newlands. Preparation of a colouring matter for and its application in the manufacture of sugar. Jan. 25.
 „ 1629. Macfarlane. Centrifugal machines for sugar. Jan. 27.
 [C.S.] 4112 (1901). Shaw. Treatment or preparation of sugar and apparatus for use therein. Jan. 25.
 „ 27,722 (1904). Ephraim. Process and apparatus for separating and recovering gum from rubber plants. Jan. 25.

XVII.—BREWING, WINES, SPIRITS, Etc.

- [A.] 659. Hunt. Manufacture of malt whiskey and of malt extract. Jan. 12.
 „ 988. Murphy. Process of filtering beer, vinegar, &c. Jan. 18.
 „ 1214. Hunt. Maturing new whiskey and grain spirit. Jan. 21.
 „ 1355. Pambur. Method and means of blending whiskey and the like. Jan. 24.
 [C.S.] 26,554 (1904). Caspar and Fitzgerald. Mashing and converting process. Jan. 18.
 „ 26,751 (1904). Hart. Method of and apparatus for use in the fining of beer and other like liquors. Jan. 18.

XVIII.—FOODS, SANITATION, WATER PURIFICATION, & DISINFECTANTS.

(A).—FOODS.

- [A.] 825. Köhler. Nutritive preparations.* Jan. 16.
 „ 1150. Bernstein. Manufacture of a substance having the properties of egg albumen. Jan. 20.
 „ 1236. Kunick. *See under XIV.*
 „ 1312. Blogg. Manufacture of culinary essences.* Jan. 23.
 „ 1609. Appleby and Banks. Treatment of food-stuffs, more especially cereals and their products. Jan. 26.
 „ 1649. Cook. Method for the production of humanised milk, and generally for rendering the milk of animals more digestible. Jan. 27.
 [C.S.] 3531 (1904). Hatmaker. Dry milk and milk-like products. Jan. 18.
 „ 22,927 (1904). Preisz. Method of sterilising food-stuffs and the like. Jan. 25.
 „ 23,100 (1904). Döllner. Production of desiccated milk and milk preparations. Feb. 1.
 „ 25,624 (1904). Székely and Kovács. Process for making an easily digestible milk preparation free from germs. Jan. 18.
 „ 27,266 (1904). Aufsberg. Process for preparing food products containing iron. Jan. 25.

B.)—SANITATION: WATER PURIFICATION.

- [A.] 916. May. *See under* H.
 .. 1143. Taylor. Contact beds and percolating filters, more especially for use in bacterial sewage purification works.* Jan. 20.

C.)—DISINFECTANTS.

- [A.] 1530. Cooke. Mercury compounds to be used for medical disinfecting and antiseptic purposes. Jan. 26.

XIX.—PAPER, PASTEBOARD, Etc.

- [A.] 143. Carr, Carr and Carr. The surfacing of water-proof papers. Jan. 10.
 .. 505. Varannes and Vains. Manufacture of paper pulp. Jan. 10.
 .. 1283. Bloxam (Verein Glanzstoff-Fabr. A. G. Elberfeld). Manufacture of threads, films, or other forms of cellulose. Jan. 23.
 .. 1284. Bloxam (Verein Glanzstoff-Fabr. A. G. Elberfeld). Manufacture of threads, films, or other forms of cellulose. Jan. 23.
 .. 1727. Bertram and Milne. Apparatus for the treatment of fibrous material to be used for the manufacture of paper. Jan. 28.
 .. 1745. Bloxam (Verein Glanzstoff-Fabr. A. G. Elberfeld). Manufacture of films, threads, or other forms of cellulose. Jan. 28.
 [C.S.] 26,953 (1903). Booth. Manufacture of printing surfaces and a composition therefor. Jan. 18.
 .. 9962 (1904). Abel (Act.-Ges. f. Anilinfabr.) Manufacture of coherent and opaque films, sheets, or masses of pyroxylin, collodion cotton, celluloid, or the like. Feb. 1.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

- [A.] 1465. Dakin. Manufacture of a group of chemical substances related to adrenalin, and of allied bodies and intermediate products. Jan. 25.
 .. 1503. Lake (California Products Co.). Process for producing cream of tartar.* Jan. 25.
 [C.S.] 5549 (1904). Richardson. Manufacture of camphors. Jan. 18.
 .. 6652 (1904). Zimmermann (Chem. Fabr. auf Actien vorm. E. Schering). Manufacture of camphor from isoborneol. Jan. 25.
 .. 23,578 (1904). Knoevenagel. Manufacture of odoriferous compounds or perfumes. Jan. 18.

- [C.S.] 28,035 (1904). Johnson (Boehringer und Soeh). Manufacture of camphor from isoborneol. Feb. 1.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

- [A.] 559. Ponton and Horne. Production of color effects on photographic paper. Jan. 11.
 .. 1290. Gillard and Molyneux. The coating or preparation of media for photographic purposes. Jan. 23.
 [C.S.] 1008 (1904). Drac. Method and apparatus for production of coloured photographs. Jan. 23.
 .. 9962 (1904). Abel (Act.-Ges. f. Anilinfabr.). *under* XIX.
 .. 27,267 (1904). Krebs. Powders or compositions for use in artificial lighting for photographic purposes. Jan. 25.
 .. 27,268 (1904). Krebs. Powders or compositions for use in artificial lighting for photographic purposes. Jan. 25.
 .. 27,465 (1904). Lüttke Arndt and Löwenberg. Flash powder for producing artificial light for photographic and other purposes. Jan. 25.
 .. 27,466 (1904). Lüttke Arndt and Löwenberg. Flash light cartridges for producing artificial light for photographic and other purposes. Feb. 1.

XXII.—EXPLOSIVES, MATCHES, Etc.

- [A.] 604. Russell. Explosives for blasting and other purposes. Jan. 12.
 .. 837. Jacob. Matches [U.S. Appl., Jan. 28, 1904]. Jan. 16.
 .. 1415. Hesketh and Willecox. Manufacture of explosives. Jan. 24.
 .. 1416. Hesketh and Willecox. Manufacture of nitroglycerine, nitrocellulose, and like explosives. Jan. 24.
 [C.S.] 23,973 (1904). Mitchell. Explosives. Feb. 1.
 .. 27,162 (1904). Allison (Muller-Jacobs). Explosive compounds and method of manufacturing the same. Feb. 1.
 .. 27,166 (1904). Lheure. Manufacture of explosives. Feb. 1.
 .. 29,056 (1904). Dittmar. Explosive or blasting compounds. Feb. 1.

XXIII.—GENERAL ANALYTICAL CHEMISTRY.

- [A.] 823. Bayer. Apparatus for analysing gases. Jan. 16.

JOURNAL OF THE Society of Chemical Industry.

A RECORD

FOR ALL INTERESTED IN CHEMICAL AND ALLIED MANUFACTURES.

ISSUED TWICE A MONTH.

No. 4.—Vol. XXIV.

FEBRUARY 28, 1905.

No. 4.—Vol. XXIV.

Subscription of Members 25 - per annum;
Entrance Fee 21 -;
Election by the Council.

Price to Non-Members 36 - per annum;
To Members 25 - per Set of extra or back numbers.
Single copies (Members and Subscribers only)
1882—1901, 2 6 each; 1902 *et seq.*, 1 9 each.

he Society of Chemical Industry.

Past Presidents:

Sir Henry E. Roscoe, B.A., D.C.L., LL.D., Ph.D., F.R.S.	1881—1882.
†Sir Frederick A. Abel, Bart., K.C.P., G.C.V.O., D.C.L., D.Sc., F.R.S.	1882—1883.
†Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, LL.D., Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Sir James Dewar, M.A., LL.D., F.R.S.	1887—1888.
Ludwig Mond, Ph.D., F.R.S.	1888—1889.
†Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
†E. Rider Cook	1890—1891.
J. Emerson Reynolds, M.D., F.R.S.	1891—1892.
Sir John Evans, K.C.B., D.C.L., LL.D., Sc.D., F.R.S.	1892—1893.
†E. C. C. Stanford	1893—1894.
T. E. Thorpe, C.B., LL.D., Sc.D., Ph.D., F.R.S.	1894—1895.
Thomas Tyrer	1895—1896.
†Edward Schunck, Ph.D., F.R.S.	1896—1897.
Frank Clowes, D.Sc.	1897—1898.
George Reilby	1898—1899.
C. F. Chandler, D.Sc., M.D., Ph.D., LL.D. C. F. Swan, D.Sc., M.A., F.R.S.	1899—1900.
Sir Jos. W. Swan, D.Sc., M.A., F.R.S.	1900—1901.
Ivan Lewinstein	1901—1903.
Sir W. Ramsay, K.C.B., D.Sc., LL.D., F.R.S.	1903—1904.

† Deceased.

THE JOURNAL.

Publication Committee:

The President.

Julian L. Baker.	Charles A. Kohn, M.Sc., Ph.D.
G. Beilby.	Ivan Lewinstein.
J. Carter Bell.	J. Lewkowitsch, Ph.D.
Joseph Bernays, M.I.C.E.	A. R. Ling.
H. Brunner.	W. Macnab.
Edw. Divers, M.D., D.Sc., F.R.S.	N. H. Martin.
Sir John Evans, K.C.B., F.R.S.	B. E. R. Newlands.
T. Fairley.	John Pattinson.
Prof. A. G. Green.	Prof. W. J. Pope, F.R.S.
Samuel Hall.	F. B. Power, Ph.D.
John Heron.	Prof. H. R. Procter.
D. B. Hewitt, M.D.	Sir Wm. Ramsay, K.C.B., F.R.S.
Prof. W. R. E. Hodgkinson, Ph.D.	Boverton Redwood, D.Sc.
E. Grant Hooper.	Walter F. Reid.
David Howard.	John Spiller.
Julius Hübner.	W. S. Squire, Ph.D.
Prof. A. K. Huntington.	L. T. Thorne, Ph.D.
Wm. Kellner, Ph.D.	Thomas Tyrer.

COUNCIL FOR YEAR ENDING JULY 1905.

President: Wm. H. Nichols, M.S., LL.D., D.Sc.

Vice-Presidents:

P. Phillips Bedson.	Ivan Lewinstein.
Virgil Coblenz.	Max Muspratt.
Edw. Divers, F.R.S.	T. J. Parker.
W. R. E. Hodgkinson.	Dr. F. B. Power.
Grant Hooper.	Sir Wm. Ramsay, K.C.B., F.R.S.
D. Howard.	Thos. Tyrer.

Ordinary Members of Council:

J. Orosmann.	B. E. R. Newlands.
Ort. Guttman.	Prof. W. J. Pope, F.R.S.
Hemingway.	Dr. Boverton Redwood.
W. R. Lang.	Walter F. Reid.
J. Lewkowitsch.	Frank Scudder.
N. L. Martin.	Dr. W. S. Squire.

Sectional Chairmen and Secretaries:

CANADIAN.	
D. F. J. Smale.	Alfred Burton.
LIVERPOOL.	
E. Ace Carey.	W. R. Hardwick.
LONDON.	
A. Gordon Salamon.	Julian L. Baker.
MANCHESTER.	
J. Carter Bell.	Julius Hübner.
NEWCASTLE.	
D. J. T. Dunn.	F. C. Garrett.
NEW YORK.	
D. Russell W. Moore.	Dr. H. Schweitzer.
NOTTINGHAM.	
J. Wood.	S. R. Trotman.
SCOTTISH.	
R. Thomson.	Dr. Thos. Gray.
SYDNEY, N.S.W.	
P. A. Liversidge, F.R.S.	T. U. Walton.
YORKSHIRE.	
P. H. R. Procter.	Thos. Fairley.

Honorary Treasurer:

Samuel Hall, East London Soap Works, Bow, E.

Honorary Foreign Secretary:

Dr. Ludwig Mond, F.R.S.

General Secretary: Charles G. Cresswell.

Office: Palace Chambers, 9, Bridge Street, Westminster, S.W.

Telegraphic Address: 59, Palatable, London.

Editor:

Watson Smith, 34, Upper Park Road, Haverstock Hill, N.W.

Assisted by the following Staff of Abstractors:

H. Ballantyne II., XII.	A. G. Levy, B.Sc. VIII., IX.
D. Bendix III.	G. W. Macdonald, } XXII.
E. Bentz IV., V., VI.	M.Sc.
J. O. Braithwaite XX.	N. H. J. Miller, Ph.D. XV
J. F. Briggs .. { XVI., XVII., XIX., XX.	C. A. Mitchell, } XII., XXII.
J. K. Burbridge XIII. C.	B.A.
T. F. Burton, } III., XX., XXI., B.Sc. Patent List.	R. W. Moore .. Trade Report.
W. A. Caspari, Ph.D. ... XI.	Barker North V., XI.
W. H. Coleman .. I., III., VII.	T. H. Pope, } XVI., XVII., B.Sc. XX., XXI.

	L. J. de Whalley, B.Sc. XVI.

Canadian Section.

Chairman: F. J. Smale.
Vice-Chairmen: (W.) H. Ellis
 Thos. Macfarlane.

Committee:

J. Watson Bain	W. R. Lamb.
Jeffrey H. Burland	A. McGill
Thos. Davies.	W. Cash Miller
G. P. Girldwood	Jas. P. Murray
W. L. Goodwin	Harold Van der Linde
Edgar B. Kentick.	

Hon. Treasurer: M. J. Taylor, 77, Front Street East, Toronto.
Hon. Local Secretary:
 Alfred Burton, 42, Front Street West, Toronto

Liverpool Section.

Chairman: Eustace Carey.
Vice-Chairman: Frank Tate.

Committee:

T. Lewis Bailey.	Max Muspratt.
G. C. Clayton.	E. L. Peck.
J. T. Conroy.	Alf. Smetham.
A. Foden.	H. B. Stocks.
G. Watson Gray.	J. W. Towers.
C. Longuet Higgins.	

Hon. Treasurer: W. P. Thompson.
Hon. Local Secretary:
 W. R. Hardwick, 13, Batavia Buildings, Hackins Hey, Liverpool.

London Section.

Chairman: A. Gordon Salamon.
Vice-Chairman: R. J. Friswell.

Committee:

H. G. Colman.	A. R. Ling.
J. N. Coman.	Wm. Pearce.
Bernard Dyer.	Boverton Redwood.
Oscar Gutfmann.	Walter F. Reid.
J. T. Hewitt.	L. T. Thorne.
D. L. Howard.	Thos. Tyrer.
J. Lewkowitsch.	Chas. Wightman.

Hon. Local Secretary:
 Julian L. Baker, 7, Addison Road, Bedford Park, W.

Manchester Section.

Chairman: J. Carter Bell.
Vice-Chairman: F. Scudder.

Committee:

J. Allan.	B. Hart.
J. Bürger.	W. B. Hart.
R. Clayton.	K. Markel.
W. H. Coleman.	W. J. Pope.
G. J. Fowler.	H. Porter.
J. Grossmann.	W. Thomson.

Hon. Local Secretary:
 Julius Hübner, Ash Villa, Cheddle Hulme, Cheshire.

Sessions 1904-5. Friday, March 3rd. Dr. J. Grossmann, "Improved Method of Indigo Testing"; Dr. Otto Oberländer, "Theory of Colouring Matters"; Mr. George H. Hurst, "Exhibition of Viscometers."

Newcastle Section.

Chairman: J. T. Dunn.
Vice-Chairman: W. L. Rennoldson.

Committee:

P. P. Bedson.	W. W. Proctor.
H. S. Collins.	Geo. Sisson.
Ellwood Holmes.	Harry Smith.
H. Louis.	A. Spiller.
N. H. Martin.	C. E. Stead.
John Pattinson.	J. E. Stuart.

Hon. Local Secretary and Treasurer:
 F. C. Garrett, Armstrong College, Newcastle-on-Tyne.

New York Section.

Chairman: Russell W. Moore.
Vice-Chairman: Geo. C. Stone.

Committee:

L. Backeland.	Wm. McMurtrie.
Chas. F. Chandler	H. A. Metz.
V. Coblenz.	Wm. H. Nichols.
G. Drobegg.	T. J. Parker.
A. H. Elliott.	F. Schniewind.
E. G. Love.	C. B. Zabriskie.

Hon. Treasurer: R. C. Woodcock.
Hon. Local Secretary:
 H. Schweitzer, 40, Stone Street, New York, U.S.A.

Nottingham Section.

Chairman: J. T. Wood.
Vice-Chairman: S. F. Burford.

Committee:

L. Archbutt.	J. O'Sullivan.
F. J. R. Carulla.	J. M. C. Paton.
R. M. Caven.	A. L. Stern.
J. Golding.	G. J. Ward.
F. Stanley Kipping.	J. White.
H. B. Mayfield.	

Hon. Treasurer: S. J. Pentecost.
Hon. Local Secretary:
 S. R. Trotman, King's Walk Chambers, Parliament Street, Nottingham.

Scottish Section.

Chairman: R. T. Thomson.
Vice-Chairman: J. S. Macarthur.

Committee:

W. S. Curphey.	Jas. Hendrick.
L. Dobbin.	Jas. Hope.
D. B. Dott.	H. Ingle.
Thos. Ewan.	W. G. Johnston.
J. Arnold Fleming.	J. Falconer King.
W. Frew.	M. A. Parker.
G. H. Gemmell.	T. L. Patterson.
R. Hamilton.	D. J. Playfair.

Hon. Secretary and Treasurer:
 Thomas Gray, c/o Gourlay and Deas, 180, Hope Street, Glasgow.

Sydney, N.S.W., Section.

Chairman: A. Liversidge.

Committee:

W. A. Dixon.	J. A. Schofield.
J. F. Elliott.	F. Greig Smith.
L. Meggitt.	H. G. Smith.
J. Morison.	T. Steel.
A. A. Ramsay.	

Hon. Local Secretary:
 T. U. Walton, Colonial Sugar Co., O'Connell Street, Sydney, N.S.W.

Yorkshire Section.

Chairman: H. R. Procter.
Vice-Chairman: G. W. Slatter.

Committee:

W. Aekroyd.	W. M. Gardner.
C. S. Bedford.	F. W. Richardson.
J. E. Bedford.	A. Smithells.
F. Branson.	Geo. Ward.
B. A. Burrell.	Thorp Whitaker.
John W. Cobb.	

Hon. Local Secretary and Treasurer:
 T. Fairley, 17, East Parade, Leeds.

Official Notices.

COMMUNICATIONS.

Authors of communications read before the Society, or of its Local Sections, are requested to take notice that Rule 43 of the Bye-laws the Society has the right of property of publication for three months of all such papers. Payment of this Bye-law renders papers liable to be selected by the Publication Committee, or ordered to be printed for the Journal, in which case no reprints can be furnished to the author.

ANNUAL GENERAL MEETING, 1905.

The Annual General Meeting will be held in London on Friday next, and the proceedings will commence on Friday, July 10th. Full particulars will appear later.

THE BRITISH SCIENCE GUILD.

The British Science Guild, which was founded some years ago by Sir Norman Lockyer, with the object of bringing home to the people of this country the necessity of applying scientific methods to all branches of human activity, has now published a first list of its members, which includes Professor Atfield, Dr. James Bell, Sir John Brunner, Professor Church, Sir William Crookes, Professor E. Divers, Dr. Gore, Dr. Griffiths, Professor Professor Liversidge, Professor Meldola, Mr. Müller, Mr. Neville, Professor Odling, Mr. Pedler, Professor Pope, Mr. V. Ramsay, Mr. Shenstone, Professor Wertheimer, Mr. Whetham, and Professor Sydney Young.

One of the principal aims of the Guild is the promotion of the extension of the application of scientific principles to industrial and general purposes—an object closely allied with that of the Society of Chemical Industry. Education, not only of the classes interested, but of the opinion in general, on this subject, is very desirable, though its progress may be slow, perhaps no surer means can be devised than that of enlisting in a single organisation all those whose sympathies are in favour of the application of exact methods in every department of science.

The annual subscription to the Guild is 2s. 6d., with entrance fee of 2s. 6d., payable to Lady Lockyer, Penywern Road, S.W. Life member's subscription is 2s. Information may be obtained from the Honorary Secretary, Mr. C. Cuthbertson, 9, York Terrace, N.W.

List of Members Elected.

February 23rd, 1905.

Areyard, J. R., Royal Technical Institute, Salford, Lecturer.
Bennett, Miss M. M., Tulane University Library, New Orleans, La., U.S.A., Librarian.
Bregard, A. P., c/o Emil Calman & Co., Long Island City, N.Y., U.S.A., Varnish Chemist.
Ben, Henry, St. Louis Chemical Co., St. Louis, Mich., U.S.A., Secretary.
Baker, A. G., 534, Canal Street, New York City, U.S.A., Agent for Kalle & Co.
Buhl, Hugo, 175, High Street, C. on M., Manchester, Chemist.
Cler, Prof. Edwin E., Longmeadow, R.I., U.S.A., Professor of Chemistry.
Cen, George H., Canton Junction, Mass., U.S.A., Manufacturer of Enamels and Dressings for Leather.

Carter, Robert A., c/o Roessler & Hasslacher Chem. Co., 100, William Street, New York City, U.S.A., Chemist.
Cormack, William, c/o Messrs. G. Nelson, Dale & Co., Ltd., Enscote Mills, Warwick, Chemist.
Cotton, W. H., The Schlüsselsburg Calico Printing Co., Schlüsselsburg, nr. St. Petersburg, Russia, Chemist.
Crosby, W., Hall Mines Smelting Co., Ltd., Nelson, B.C., Canada, Chemist.
Davidson, Thomas A., c/o Jos. Watson & Sons, Ltd., and 20, Cromer Terrace, Leeds, Chemist (Glycerin Distillery).
Dickinson, Cyril, "Abbotsford," Hollycroft Avenue, Hampstead, N.W., Analytical Chemist.
Eagen, N.B., Toronto, Canada, Barrister.
Fiebiger, Peter, 530, Canal Street, New York City, U.S.A., Colour Chemist.
Gallinagh, James P., Electricity Works, Limerick, Ireland, Borough Electrical Engineer.
Geisenheimer, Albert, P.O. Box 994, New York City, U.S.A., Dyestuff Merchant.
Gilbertson, I. H., 5, Broad Street, Rhodes, nr. Middleton, Lancs., Calico Printer.
Grip, August E., 194, Lee Avenue, Brooklyn, N.Y., U.S.A., Chemical Engineer.
Harcourt, Prof. R., Ontario Agricultural College, Guelph, Ont., Canada, Professor of Chemistry.
Hawley, Fred. G., La Cananea, Box 10, Sonora, Mexico, Assayer and Chemist.
Henning, Albert, 92, Harrow Road, Leytonstone, N.E., Chemical Manufacturer.
Hoppenstedt, A. W., 138, Joralemon Street, Brooklyn, N.Y., U.S.A., Chemist.
Kirkland, John, 8, Corrance Road, Brixton, S.W., Technical Instructor.
Knapp, Sewell A., Tonopah, Nevada, U.S.A., Mine Manager.
McDowell, Stewart H., 1246, South 51st Street, Philadelphia, Pa., U.S.A.
Marland, Percy, c/o Brotherton & Co., Ltd., Ammonia Works, Wakefield, Works Chemist.
Marlatt, W. T., Oakville, Ont., Canada, Leather Manufacturer.
Merek, George, Merek & Co., University Place, New York City, U.S.A., Manufacturing Chemist.
Merzbacher, Aaron, Laboratory of Reading Iron Co., Reading, Pa., U.S.A., Chemist.
Moorwood, F. Colin, c/o Floekton Tompkin & Co., Ltd., Newhall Steel Works, Sheffield, Steel Manufacturer.
Mrazsek, F. M., 29, Mincing Lane, London, E.C., Consulting Chemist.
Needham, Edwd. R., 48, Paton Street, Glasgow, Manufacturing Chemist.
Peet, W. J., Stock Yards Station, Kansas City, Kas., U.S.A., Superintendent.
Pirie, F. D., Stonewood Works, Bucksburn, Aberdeen-shire, Paper Manufacturer.
Pitcock, C. K., Baithney Estate, Saklaspur, Hassan, India, Coffee Grower and Chemist.
Queiroz, Dr. L. M. Pinto de, Rue Direita 10 B., Sao Paulo, Brazil, Manufacturing and Wholesale Chemist.
Safford, E. Brigham, Albuquerque, New Mexico, U.S.A., Chemist.
Schmidt, Herman B., 2523, Essex Place, W.W.H., Cincinnati, Ohio, U.S.A., Manufacturing Chemist.
Simpson, Edward H., 52, Park Street, Jersey City, N.J., U.S.A., Chemist.
Smith, Arthur, Towend Chemical Works, Bramley, Leeds, Chemical Manufacturer.
Smith, C. E., Herolds' Institute, Drummond Road, Bermondsey, S.E., Tanner.

Stahl, P. G., 10, Rue des Canonniers, Lille (Nord), France; Chemical Manufacturer.

Stamp, Edward, Florence House, Dewsnap Lane, Dukinfield, Sewage Works Manager.

Turnbull, John, 66, Jarvis Street, Toronto, Canada; Manufacturer of Food Products.

Watt, Dr. Ida, 73, West 83rd Street, New York City, U.S.A.; Chemist.

Wyer, M. de G., State University, Iowa City, Iowa, U.S.A.; Librarian.

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps in the verification of addresses, on which the safe delivery of the Journal depends.

Andrews, Wm. H.; all communications to 79, Tonawanda Street, Buffalo, N.Y., U.S.A.

Meeting held at Manchester, on Friday, January 13th, 1905.

MR. J. CARTER BELL IN THE CHAIR.

MOISTURE TESTS OF WOOD PULP.

PART II.*

BY J. H. LESTER, M.Sc., F.I.C.

During the summer of 1903 the writer was asked to visit a Norwegian pulp mill, with the object of examining and improving the methods of testing there adopted in determining the moisture in bales of wood pulp; the owners of the mill being anxious to explain, if possible, the differences in result as between their own tests and the tests made upon the same bales by the buyers of the pulp in Lancashire.

A week was spent at the pulp mill in making a number of comparative tests intended to demonstrate the correctness of the methods whereby freshly packed moist pulp may be tested for moisture. A quantity of pulp was then selected, sampled, weighed, packed, shipped to the Lancashire paper mill, reweighed and retested so as to afford a means of comparison between an ordinary pulp mill test and a paper mill test, made upon the same bales after shipping and storage.

FIRST SERIES OF TESTS.—The method of sampling adopted by the pulp mill previous to my visit was that of picking out two strips from each sheet

method alone can be correct when the outside edges of a sheet are either much drier or much wetter than the centre, but that the method adopted in sampling becomes of less importance as the sheets approach uniformity, and, of course, a sheet that is of uniform moisture throughout may be sampled correctly without any attempt to observe rules of any kind. The above series gives practical proof of the correctness of the theory as applied to a somewhat abnormal sheet. The next series refers to normal sheets.

SECOND SERIES OF TESTS.—These tests were intended to show the difference in result actually to be found in practice according to the method of cutting samples, the first series having reference to a special case.

Procedure.—(A2) 18 or 20 sheets were selected from various parts of several truck loads of sheets awaiting final packing; the samples were selected representing four or five bales. The "mill method" of sampling was adopted, as in C, Fig. 1.

(B2) Wedge-shaped samples were cut as in B, Fig. 1, and dried.

The results are given in Table II.

Conclusions.—That a difference of 1.2 per cent. on the absolutely dry figure, or 2.6 per cent. on the "50 per cent. air-dry pulp" figure may be considered likely to result according to the method of sampling freshly packed pulp.

THIRD SERIES OF TESTS.—The object of the tests was to confirm the previous series. As in the last series, except that the wedge samples were alternately cut transversely and diagonally from the sheets. This method of cutting is theoretically preferable to that adopted in the previous series.

The results are given in Table III.

Conclusions.—That a difference of 1.3 per cent. on the absolutely dry figure, or 3 per cent. on the "50 per cent. air-dry figure" may be considered likely to result between the two methods of sampling as applied to freshly packed moist pulp. The agreement between the second and third series is sufficiently close.

FOURTH SERIES OF TESTS.—These tests were made to show the actual difference in percentage of moisture between the outside edges and the middle of the sheets.

A representative sheet was selected from the press, and the outer edge was cut away to a distance of 1 in. to 1½ in. to form the "edge" sample. An "intermediate" sample was next cut to a width of 2 in. or 3 in. all round the sheet, and the remainder of the sheet was taken as the "middle" sample.

The results are set forth in Table IV.

Conclusions.—(1) That the difference in moisture existing between the outer edges and the middle of a sheet of freshly packed pulp is quite enough to account for the difference in results, which follows from different methods of sampling.

(2) Since the whole sheet contained 50.7 per cent. of moisture and the intermediate portion contained 52.6 per cent., it would appear unlikely that any one or more circumscribed areas in the sheet can be found where a representative sample may be drawn. If such positions do exist, they must be less than 2 in. from the edge of such sheets as those experimented upon.

FIFTH SERIES OF TESTS.—These tests were commenced at the pulp mill with the object of showing whether similar results would follow a second sampling and testing after shipment to England and storage. It may be urged that since the bales could not possibly lose anything but moisture in transit, that the same dry contents should be found at whatever time in the life of the bale it chanced to be tested. This is quite true, but it has frequently been alleged that a fair test of a bale could not be made if that bale happened to have been exposed for an undue length of time to wetting or drying influences, and the alleged impossibility of obtaining a really representative sample has been quoted as an explanation of the differing results obtained by pulp maker and paper maker. There is no doubt whatever that their results do frequently disagree.

Procedure in Norway.—Five bales of pulp were made up to a weight of 448 lb. each, after sampling in five places by the cutting out of "wedges." It should be noted that all the samples in this case were cut to the same base length and not according to the method necessary in this

Fig. 1.

with the point of a knife, as shown at C in Fig. 1. It was the object of demonstrating the inaccuracy of this method and the substantial accuracy of the wedge method, that this series was undertaken.

Procedure.—(A) A doubled sheet of pressed pulp, measuring 24 in. by 18 in. in each fold, was selected from the pressed pulp lying ready for packing, and one-half of it (A) was dried. The sheet chosen for the tests was distinctly wetter at its extreme edges than most of the other sheets; the object of this choice was to accentuate any differences due to methods of sampling.

(3) The fold of pulp adjoining A was sampled according to the method shown at B Fig. 1.

(4) Small pieces of pulp were chipped out of position B Fig. 1 from the same sheet that B was taken.

(5) Samples were cut by the wedge method from the middle of the four sides to the centre of the sheet: B, C, D, being all cut from the same sheet.

The results of the above tests are given in Table I.

Conclusions.—(1) That so far as freshly packed moist pulp is concerned, the wedge method of sampling gives a correct result, because it is practically identical with the result of drying the whole sheet.

(2) That the "mill method," as well as another very similar method sometimes adopted in this country, does not show the amount of moisture that is contained in the whole sheet of freshly packed pulp.

It follows from the theoretical considerations set forth by the writer in 1902 (this J., *loc. cit.*) that the wedge

* Part I. of this paper appeared in this J., 1902, 380.

country for bales that have been shipped or stored. The variation in length of the base of the samples is only of consequence where we are endeavouring to obtain some representation of the outermost sheets of a bale without unduly increasing the size of the bulk sample. A second lot of 5 bales were similarly selected and sampled, and with the first lot were made up in the ordinary manner with canvas and wire, distinctively marked, and shipped to the Lancashire paper mill for further test.

The result of the remaining tests are given in Table V.

Procedure in Lancashire.—Lot A. (See Table V.) The bales were found to have arrived at the paper mill in good condition owing to the special care taken of them in transit to avoid exposure to rain, sea water or undue drying influence. Exactly one month from the time of packing in Norway, the bales were weighed and tested with the results given in Table V., Lot A.

Lot B. These bales were allowed to lie for nearly six months from the time of packing, in the paper mill warehouse. The place of storage was a large upper room mostly filled with similar bales of the same brand of moist pulp so that the conditions of drying would be as nearly as possible the same as in the ordinary routine of a paper mill. Instructions were given to have the bales turned over on to a fresh end or side every week, to prevent uneven drying and this is believed to have been done. At the end of the six months, the bales were weighed and tested with the results shown in Table V., Lot B.

Conclusions.—(1) That bales of pulp which have lost weight to a considerable extent by drying may still be reliably tested, as regards their dry contents, by the wedge method. We may infer that bales which have been externally wetted during transit may be similarly tested with reasonable accuracy since the wetting probably affects the bale with the same progressive action from the outside to the centre of the bale, though reversed in point of dryness and moisture.

(2) The variation in weight of the separate bales of a consignment, commonly noticed when they are received in this country, is not of necessity due to some having been carried as deck cargo or some having been stored against the boilers, but that differences of at least 2 per cent. in weight are certain to arise between separate bales owing either to different conditions of their exposure to air or to a actual variation in moisture at the time of packing and consequent difference in rate of drying.

(3) That 50 per cent. pulp should not dry to a greater extent than 2 per cent. in one month nor more than 6 per cent. in six months under ordinary conditions.

(4) That so far as the middle sheets taken from bales of moist pulp are concerned, the centre of the sheets is distinctly drier than the outside edges, even after storage for six months. I may here remark that the last-mentioned result was quite unexpected and shows that the drying of a bale of wood pulp is by no means the simple affair that might have been supposed. It needs no proof to convince ourselves that the final drying stage will be that in which the bale is uniformly dry throughout its bulk with the exception of a damp spot at the centre, but the intermediate stages are greatly complicated by the fact that the bale appears to resist drying through the various sheets (or from sheet to sheet) whereas drying may go on rapidly from one part of the sheet to another. The foregoing explanation would appear at first sight incorrect in view of the fact that far more moisture exists at the edge of the middle sheets than at the top and bottom sheets of the bale; but this apparent conflict vanishes when we consider that that outside part of the bale which is the most damp is probably giving up its moisture to the air at the greatest speed. The tendency of blotting paper to absorb moisture more rapidly in the direction of the fibres than through superimposed layers is well known and we may reasonably expect that the drying of wood pulp bales may be explained in exactly reverse direction. If a further set of samples had been drawn from the most extreme edge of the sheets referred to (say, only 1/16th in. wide), it is highly probable that less moisture would have been found.

An attempt has been made with partial success to graphically describe the distribution of moisture in a

bale of pulp which has dried for some months. The bale is supposed to be in vertical section with the sheets in a horizontal position, and the lines are intended to show isohygric. (Fig. II.)

Fig. II.

(5) It would have been interesting to have made comparisons between the results obtained from various methods of sampling, but although a few such tests actually been made, none are quoted here for which it is, however, necessary to state. I am not that any one, other than the writer, has defined a precise position in the bale from which the sheet sampling are to be selected though it is true that the advisability of taking a large number of sheets at distances apart has been frequently and quite correctly advanced. Methods other than that of the "we" will give results less or greater than the truth according to the position in the bale from which the sheet is selected and, again, these methods have already been sufficiently discounted by other means. We will, however, briefly note the difference arising by selection of sheets from different positions.

Referring to Lot B tested after six months' storage we find that the "50 per cent. air-dry contents" is 107.4 per cent. by correct sampling of the bale, showing practical agreement with the content of absolutely dry pulp found at the pulp mill. If the bale had been sampled by cutting wedges of equal size from the seventh sheet as well as from two representative inner sheets the figure would have been 110.0 per cent. To go to the other extreme, if the outer seven sheets from the top and bottom of the bales had been rejected and the rest of the bales properly sampled we should have found 105.5 per cent. These are the differences which must be expected to follow the adoption of incorrect methods of sampling; they are directly deduced from the results stated in the tables. They are different depending not upon the correctness or incorrectness of the wedge method, but simply upon the position of selection of samples from the bale and upon the sizes of separate pieces.

We may now summarise conclusion No. 5 by the statement that no method of sampling can give a correct or even a uniform result unless it defines the position in the bale whence the sheets are to be taken for sampling. Again, if the samples are to be of equal size it will be necessary to test a great number of sheets from each bale.

A few notes made at the pulp mill concerning the circumstances which influence the amount of moisture in the pulp will not, I think, be out of place in conclusion. Many of them, perhaps all, are known to some pulp makers, but the list is made as full as may be with the object of showing a few of the difficulties which the producer experiences in meeting the requirements of the consumer for a uniform percentage of air-dry pulp. They may be of use to some pulp makers who have not given special attention to the matter.

CIRCUMSTANCES CONTROLLING THE MOISTURE CONTENT OF PULP.—

(1) It is self evident that if other conditions are equal, the fineness of grinding of the pulp will influence the result, apparently causing a finely ground pulp to retain more moisture than if coarsely ground.

) The amount of water contained in the pulp before pressing is likely to have some influence upon the content of the final product.

(2) The thickness of the sheet before pressing would appear to influence the result although a single test made for the object of proving this yielded a negative result. A ingenious device for obtaining uniformity of thickness involving the striking of a gong when the sheet has a given thickness has been introduced but was an unqualified success. If an even supply of pulp could be depended upon it is clear that the thickness of sheet would be proportionate to the revolutions of the roller upon which it is taken up and an automatic device for stripping the roll or "doffing the blanket" could be devised. It is, however, probable that in some cases the flow of pulp is very far from uniform. Some have recently been made upon large consignments of pulp in which the sheets were distinctly thicker than usual and a great excess of moisture has certainly been found. (A well-known paper maker attributes excess of moisture in Canadian pulp to greater length of fibre as compared with Scandinavian pulp.)

(3) The time of exposure of sheets to hydraulic pressure may be regarded in practice as of more importance within limits than the pressure itself. Economy of time is said to result from relieving the pressure for a few moments during the operation as compared with continuous pressing. After the pressure has reached its maximum and whilst it is maintained there, the water seems to pour out for many minutes at apparently the same rate, whereas slight increases of pressure have little effect upon the flow.

(4) The kind of cloth used for pressing certainly has its influence upon the moisture contents of the pulp. A casual inspection giving the impression that cocoanut fibre was preferable to cotton, wool or hemp cloths. It would be an easy matter to compare results from various materials. One of the Canadian mills appears to use wire but wire "cloths," the mesh being about $\frac{1}{2}$ in. are used and the wire of about 12 B.W.G. It would appear that more uniform results as regards moisture should be obtained by the use of these wire cloths than where tiles are used and the Scandinavian mills would certainly be well advised to experiment in this direction. It must not be assumed for one moment that Canadian pulp is more uniform as regards moisture than Scandinavian.

(5) The size of the sheets or folds has a direct influence on the moisture, though this is another case where experimental proof is wanting. For the same pressure, it is obvious that small sheets are preferable to large ones, the pressure per square inch of pulp being greater. Again, if the sheets are small the moisture will be able to get away much more rapidly than from large sheets. If the pressure per square inch of surface of pulp is the same. Bales packed from large sheets cannot withstand the rough usage to which they are subjected in transit and no sheets of moist pulp should measure more than 24 in. by 18 in. The depth of the bale may conveniently be 30 in. If well packed the above dimensions will yield a 4 cwt. bale that should lose nothing in transit. The canvas used for the purpose is too frequently of inferior quality. I may remark that the pulp upon which I carried out the above tests and answers to the above dimensions is equal to anything I have seen as regards appearance after shipping. I have known badly packed pulp to lose over 1 per cent. through edges of pulp being broken off the bales at the quay side; loss between the pulp and paper mills must have been considerable.

(6) It is clear that the condition of the mats as regards freedom from fibres of pulp will affect their efficiency in removing moisture from the sheets of pulp. These mats should be washed as often as possible, and it is much better to wash a few at a time frequently than to wash them altogether at long intervals. The latter procedure is likely to result in the whole output varying in moisture contents according to the condition of all the mats.

(7) There is likely to be a little difference between the sheets turned out from the top and bottom of the press, but since sheets of iron are generally placed at intervals

between the sheets and the pressure is almost the same from top to bottom, this may be almost negligible. The edges of the lower sheets are of course exposed to more water trickling down from above.

(8) I am told that some mills press a definite number of sheets until the table has risen to a given point, this method being supposed to yield uniform results as to moisture contents. The method is only mentioned to condemn it, the obviously correct course being to work to a given hydraulic pressure varying, of course, with the size of the sheet.

CONCLUSION.—I have frequently been asked to state what I consider the best method of selecting samples of pulp, but I have always found much difficulty in giving a short answer to this question. Circumstances vary so greatly that it is difficult to lay down a hard and fast rule. The principles of sampling must be understood and applied to each case arising. It is therefore somewhat grudgingly, and as a concession to those who would have everything standardised or converted to a more mechanical movement, that I attempt to describe the best practical means of testing pulp.

Selection of bales.—Bales from which pieces of pulp have been broken off, bales with all wires broken off, in short, all bales that are not "intact" must be rejected from the test. Bales that have obviously been carried as "deck cargo" should be rejected, and, according to the recommendations of the British Wood Pulp Association, all bales of abnormal weight should also be rejected. (The acceptance or rejection of bales should rest with the analyst, if an absolutely impartial test is required, since the exclusion of over damp light bales would be obviously unfair to the buyer.) The bales to be tested should be selected by the analyst who undertakes the test, and he may have to reject bales which have been specially put to one side for the purpose of testing. If the consignment has not all been delivered at the time of sampling, some of the selected bales may be taken from waggons or loads arriving during the test. As far as possible, the sample bales should be taken from "all parts" of the stock available.

Weighing.—As a rule, a platform weighing machine will be provided for weighing the bales, and unless there is some good reason to the contrary, several bales should be weighed at the same time. This procedure reduces the error of weighing the bales singly. For instance, if the machine will only turn with 4 oz., we may suppose that error to apply to each weighing. If the bales are weighed singly, the error is 4 oz. per bale, but if in fours the error is only 1 oz. per bale. It is well to bear in mind that every error made in testing is multiplied 50 fold, as applied to the final result of the test—assuming that the usual 2 per cent. test is being made. When bales are numbered progressively, it is generally advisable to note the number of each weighed bale, this being often asked for by the pulp maker when too late. So far as the analyst is concerned, the progressive numbering of bales is of use in helping him to obtain representative bales; he should certainly avoid including several consecutively numbered bales in his test.

Sampling.—If many bales have to be sampled, a good deal of time can be saved by employing one person to weigh and another to cut samples. If it is convenient to open the bales close to the weighing machine, any intelligent person may be allowed to weigh the bales, but the analyst will see each one balanced and record the weight himself. If the bale under test is about 24 in. in thickness, the sheets for testing may be selected from the middle, and at $1\frac{1}{2}$ in. from the top and bottom. Four "wedges" are cut from each of these sheets, the base length of these from the middle sheet being 6 in. and the base length of these from the outer sheet 1 in. (Fig. III.) If the sample produced in this manner would be too large to dry conveniently in the ovens at disposal, the wedges may have base lengths of 3 in. and $\frac{1}{2}$ in., or two wedges only may be cut from each sheet. In very large consignments, it may be sufficient to take only one wedge from each sheet. The reasons for the above procedure have already been set forth (J.S.C.F., *loc. cit.*), though the practice advised is slightly simplified and modified in the light of results now given, particularly

view of the extent and fact of moisture travelling with difficulty through the several sheets, but readily along a cross the sheets. It is now assumed that a sample sheet taken from near the middle of the bale will represent the moisture contained up to within 3 in. of the top or bottom of the bale. Occasions may arise when for some special reason it will be advisable to vary the above method. For instance, if only five bales of pulp have to be tested, it will be better to take a whole sheet from the middle of the bale and wedges from the outer sheets equivalent to one-sixth of that sheet. An extreme case would be that of sampling a single bale

where six entire sheets would be taken to represent the middle of the bale, a full sheet from points $1\frac{1}{2}$ in. from top and bottom. This latter method is equivalent to the collection of six sheets from equal distances apart throughout the bale. Only one other extreme or exceptional case need be mentioned, and that is the case sampling pulp where the excessive moistening or drying influence has only affected the extreme outside edge and outermost sheet of the bale. The outermost sheet may then be selected at $\frac{1}{2}$ in. from top and bottom of the bale and the outer wedges must be about one-twentieth of the area of the

wedge taken from the middle sheet.

The writer desires to acknowledge his indebtedness to the following gentlemen who have shown him great kindness, and without whose co-operation the paper would not have been written.

Mads Henrik Smith, Esq., T. Thommesen, Esq., Björnness, Esq., and Mr. Peterson, of the Rygene Træmassefabrikker Aktieselskab, and Mr. Watson, of the Darwen Paper Mill Co. Particular mention should be made of the fact that the Rygene Company were not only willing but anxious for any information obtained in their mill to be used for the information of the industry as a whole.

Tests made at the Pulp Mill in Norway:—

Outer parts or "edges"	44.09%	46.60%
Closest sheets, average	64.36%	64.13%
Inner sheets from top and bottom of bale	(not done)	57.61%
Moisture " " "	48.69%	53.52%
Moisture sheets	46.20%	47.41%

DISCUSSION.

The CHAIRMAN remarked that everyone was familiar with the difficulties attending the sampling of paper pulp, the various methods of testing for moisture. On comparing his notes of several tests which he had made was inclined to think that the wedge-shaped sample suggested by Mr. Lester was more accurate, although could not see why holes bored in the bale, similar to the method adopted in sampling cheese, should not give a fair average result of the moisture.

Mr. H. L. TERRY thought that the phenomena of segregation, as exhibited by metallic castings, formed an interesting parallel to the variable distribution of water in wood pulp. A non-expert in either case might easily fall into grave error when taking samples for analysis. He would like to know whether sulphate and sulphite pulp showed variations in water content, as marked as those seen by Mr. Lester to occur in the case of mechanical pulp.

Mr. H. PORTER said he had had experience in testing for moisture in gun-cotton charges, which required to be very fully compressed, and it occurred to him that the difficulties were somewhat the same. There was a certain amount of spring after it had been under compression for some time. If a circular gun-cotton charge were halved the centre core was found to be much harder than the outside, and the springing was a very important factor with regard to the moisture evaporating, or being absorbed in the charge. In gun-cotton charges holes were pierced through the centre, and if it were possible to adopt this case with bales of wood pulp a much more uniform test for moisture would be possible.

Mr. G. H. HURST said that the various methods of testing wood pulp had always been a bone of contention between the Norwegian pulp makers and the Lancashire paper manufacturers. He thought the wedge-shaped sample gave the most accurate results. Every parcel should be considered separately, as there was considerable difference in the condition of each parcel, and there were distinct cases that the pulp maker had mixed different batches of pulp together. Mr. Lester had done good in the direction of showing the Norwegian pulp manufacturer that taking samples from the middle of the bale did not give exactly the same results, and that, by using the wedge method, much more accurate results could be obtained. No doubt there was a want of agreement between experts as to the best methods of sampling, and he thought Mr. Lester's paper would contribute towards that end.

Mr. JULIUS HÜBNER said that the question of pulp testing was of the greatest interest not only from a commercial point of view, but also from a scientific standpoint. He considered that it should not be impossible to establish a method, based on scientific principles, of sampling wood pulp by means of which the possible error would be reduced to a minimum. The testing of wood pulp was, after all, similar to the testing of cotton yarn, and it would, therefore, be only a question of extensive experimental research to establish a reliable method of sampling. As long as this remained to be done, it was, in his opinion, of great importance that those engaged in testing pulp should agree upon one

method of sampling. If this could not be conveniently brought about, then there was only one way to solve the question in a satisfactory manner, namely, the establishment, by those concerned, of a testing institute to which all the tests would be referred.

Mr. Wm. THOMSON was of opinion that it would be impossible to determine with absolute precision the quantity of water existing in a bale of wood pulp; but he was afraid that the sellers would not be satisfied with the form of test suggested by Mr. Hübner. It seemed to him that whilst the wedge-shaped cutting suggested by Mr. Lester might accurately give the percentage of water in the sheet, it would not necessarily give the percentage in the bale. It would be interesting as a test of the accuracy of water determination to take a certain weight of thoroughly dried wood pulp and make a bale of it, and then make tests by cutting samples from different sheets and comparing the result with the actual percentage known to be present.

Mr. J. GROSSMANN thought that it would have been preferable if Mr. Lester had expressed his results in the usual graphic form of curves; and that it might be possible to select the samples always from a number of definite points in the bale, and that the positions of these points could be determined from a large number of samples taken from standard bales.

Mr. J. H. LESTER, in reply, thought that the suggested parallel case of the segregation of metals had some bearing on the subject, and that further investigation on these lines would be profitable. As to testing of sulphite and sulphate pulp, they would be treated in precisely the same manner as mechanical pulp; the question being that of obtaining a correct proportion of the inside and the outside parts of the bale. The spring of gun-cotton charges was also an interesting parallel, and might have its application to pulp testing. With regard to the suggestion to bore holes through the bales to be sampled, he (Mr. Lester) referred to his previous paper where, in diagram No. 15, he showed that the samples must be of a conical form and must not be cylindrical. With regard to the testing of cotton yarn or bales of cotton, his methods might be applied to all materials packed in bales or cases where the outside of the goods were liable to be affected by moisture or dryness. The wedge method included more of the outside of the pulp than any other method, although it was shown in the previous paper that, if anything, the wedge method did not include quite sufficient of the outside pulp when considered geometrically. Investigation would have to be considerably extended to allow of graphic curves being used in illustration, inasmuch as numerous points on the curve would have to be found. [Mr. Lester here illustrated the probable character of the curve on the blackboard.] No definite point could be found in the bale which would apply to varying conditions of external drying. The method of testing suggested by Mr. Thomson was theoretically perhaps the best that could be devised; it was better than the wedge method. Unfortunately paper makers would not give the time and labour necessary to carrying out such a test. With regard to Mr. Thomson's assumption that a bale containing moisture only at the centre would be incorrectly sampled by the wedge method, he thought his method would apply correctly to such a case, as had been shown in the geometrical proofs of the previous paper.

RUSSELL W. MOORE IN THE CHAIR

STANDARDS OF PURITY FOR FERMENTED AND DISTILLED LIQUORS

BY PHILIP SCHODDOWITZ, PH.D., F.R.S.

The subject of these remarks forms only a small part of the important general question of the purity and composition of articles of food and drink as a whole. My reason, however, for confining these notes to the articles designated in the above title is that I prefer to speak only with regard to matters of which I have some special experience.

Broadly speaking, there are two main factors to be considered in the food problem, namely, adulteration proper and misdescription. To a certain extent these problems overlap, but on the whole they are fairly well differentiated. Practically there is very seldom any doubt in the mind, either of the food expert, or the merchant, or of the lawyer in cases of adulteration proper, but where misdescription, or alleged misdescription is concerned, serious and perfectly genuine differences of opinion are of frequent occurrence.

In such cases, the fixing of any standard, more particularly with respect to manufactured articles, such as beer and spirits, be it in regard to the nature of the raw materials, or to the method of manufacture, or to the composition of the ultimate product, is a matter of the greatest difficulty. Broadly speaking, the questions which have been raised in this connection in the fermentation and distillation industries have been concerned, firstly, with the source from which the alcohol is derived, and secondly, in the case of spirits, with the type of still employed. The discussions which have arisen in connection with these matters have, no doubt, in part, been due to or have been influenced by, various trade interests, by political motives or by an excess of zeal or by a lack of technical knowledge on the part of the hygienist or chemist, but on the whole, I think, they have been normal manifestations of the ceaseless struggle which is being waged with a view to the differentiation in every individual case between that which is legitimate and that which is an undesirable application of science. Before discussing the question of standard of purity as such, it may not be out of place to give a few instances of our experience in recent times in England in connection with these matters.

At the beginning of the nineties, a Royal Commission was appointed to inquire into the conditions of manufacture and storage, &c., of British and foreign spirits. This commission chiefly devoted its labours to whisky. The practical outcome was that the Commission found it neither necessary nor equitable to restrict the term "whisky" to a product made from any one particular material, or to a spirit made in any specific type or still. It may be added that in Scotland, whisky, as the term is understood in that country, is made solely from cereal grains, and that no sugar nor essences of any kind are employed in its manufacture. The official regulations concerning the treatment of spirits in bond, in fact, preclude the possibility of passing out of bond as "Scotch Whisky" an article sophisticated in any way. Practically all the whisky exported is exported from bond.

The more or less recent experience of arsenical poisoning must be fresh in your minds, and the Royal Commission appointed to inquire into this found that with ordinary care brewing sugars and malts could be prepared practically free from arsenic, and they made recommendations as to the laying down of some fixed standards which should delimit the amount of arsenic permissible in any brewing material.

Coming to more recent times, it is of interest to allude to the prosecutions instituted during the past year in the

United Kingdom in connection with the sale of spurious brandy. These prosecutions are mainly of interest inasmuch as they resulted in the practical establishment—for the first time, to the best of my knowledge—of a definite chemical standard in connection with a distilled liquor. It was held by the magistrate in a test case, that brandy should contain approximately 80 grms. of compound ethers for every 100 litres of absolute alcohol. This standard is now generally acted upon in England, although, of course, it has not the force of a statute. Persons I think it very regrettable that this standard should have been set up, my reason being that, in the first place, within my experience extremely unwise, in the majority of cases, to be guided as to the purity of a fermented distilled liquor by a single analytical figure, and that in the second place, such a standard is nothing more than a premium upon adulteration. In plain words it has led, as anyone versed in such matters must have foreseen, to the direct addition, by unscrupulous parties, of compound ethers to spirits which certainly do deserve the name of "brandy." One could not have more striking example of the dangers to which false chemical standards, particularly when confined to a single figure, may lead.

I now come to the discussion of the general lines which, according to my opinion and experience, stand out as the principle of purity for fermented and distilled liquors may be rationally considered. As this is a question of particular interest in this country at the present time, I take liberty of using, as a basis for my remarks, the suggestion made by the Chief of the Bureau of Chemistry of the Department of Agriculture to importers in Circular No. 18 (August, 1904). I hope it will not be considered presumptuous on my part, if, to begin with, I venture to congratulate Dr. Wiley and the U.S. authorities on their energetic and courageous efforts which they are making for the solution of the great problem of food adulteration and misdescription.

I take the different articles in the order enumerated in the circular alluded to.

Wine.—No honest or sensible person will object to the principle that wine should be correctly labelled as to its class, country or origin, &c. I doubt, however, whether the administrative machinery of all the countries concerned suffices for the provision of an absolute official guarantee or pedigree in all cases, and whether serious differences of opinion with regard to definitions, tending to dislocate international trade, may not arise, if any hard and fast, non-flexible regulations, are made in this connection. I do not doubt, however, that a thorough discussion of these matters between representative of the countries and industries concerned would lead to a good working arrangement.

With regard to the question of sulphurous acid in wines, I think that the limit for free acid suggested, namely, 20 mg. per litre is somewhat low. In the case of certain sweet wines, such as the Chateau Yquem, which require very frequent rackings, I do not think that a limit of 400 mg. of total sulphurous acid, and, of 30 to 40 mg. of free acid would be excessive. It must be remembered that these are very heavy wines, and that they are only consumed in small quantities. I understand that the French Government has recently adopted a standard of 440 mg. as their limit.

It is suggested in the circular alluded to, that all wines containing more than 11 per cent. of alcohol by volume, shall be classed as "fortified." This, within my experience, would constitute an injustice to certain natural wines, such as some of the heavier Burgundies, Spanish and Italian wines. I may be excused for quoting a few figures from my note book for the past ten years in this connection. These wines, I have the best reason for believing, came to me in a natural state: Alicante 17 and 15.51 vol. per cent. of alcohol respectively; Burgundies 14.53, 14.01, 14.20, 14.05, 14.10, 14.38, 14 and 14.48 per cent. respectively.

Some of the clarets of the famous 1900 vintage obtained as much as 13.76, 13.71, and 13.40 per cent. of alcohol naturally. In a table, issued by the Italian Ministry of Agriculture (Rome, 1896), out of 11,999 wines, 1221, that is, somewhat over 10 per cent., contained

naturally between 14 and 15 per cent. of alcohol, and at 2 per cent. of the wines contained over 15 per cent. alcohol.

It is within my experience extremely dangerous to use as a standard of purity for wine any single figure. Judging a wine it is necessary to make a complete analysis, to compare the figures so obtained with the published data, and finally to consider whether there are special circumstances affecting the case in point. In case of doubt I think it is desirable that the chemist should call in the assistance of an expert taster.

Brandy.—It is a matter for congratulation that Dr. Wiley has not suggested any minimum limit for any of secondary products such as the compound ethers.* I have indicated above the evils which may result from a course. On the whole, I venture to think that proposed standards for brandy are both fair and unable, but I do not agree with Dr. Wiley that the act of storage in wood is the elimination of fusel oil (higher alcohols). My experience is that, broadly speaking, mature spirits contain rather more of the higher alcohols than do raw spirits. I ascribe the maturation of spirits to the conjoint effect of a variety of circumstances, which I hope to allude in detail in a subsequent paper. It is sufficient to say that there is no experimental evidence in literature confirmative of the generally-held view that higher alcohols disappear during maturation, and, theoretically regarded, there is no particular reason why they should do so.

In my opinion the analysis of brandy, as generally carried out at present in France and in England, is useful in a negative sense; that is, if the figures as a whole below the limits indicated by experience as being normal for a genuine spirit, it may be regarded as prepositive evidence that the spirit is not genuine. For example, a sample having, say roughly, 150 mg. of total secondary products and 30-40 mg. of ethers,† and practically no furfural would obviously be open to grave suspicion. But each case should be considered on its merits, and no conclusion should be drawn from a single figure. On the other hand, a sample which is analytically satisfactory is not necessarily genuine. In cases of doubt, a taster's assistance should be requisitioned. If both the opinion of the analyst and of an unprejudiced taster are adverse to a sample, the merchant or distiller should be called on to give evidence as to the origin, &c.

Whisky.—The remarks with regard to fusel oil made for brandy apply also to whisky. I think on the whole the limit of 0.25 per cent. of fusel oil, suggested by Dr. Wiley, will not inconvenience the whisky distiller, but I nevertheless fear that it may occasionally tend to cut out a very fine, "big," genuine spirit. I would suggest 0.1 per cent as a safer limit. It should be remembered that the determination of fusel oil is by no means an easy matter, and that even the best processes are liable at times to give results open to suspicion. In a former paper (J., June, 1902) I stated that the official German (50) method could not be used for whisky, and further experience since then has confirmed this view. A large number of experiments have indicated that the only

trustworthy method is that of Allen-Marquardt; but even this method occasionally gives somewhat anomalous results. I have recently found that the French colorimetric method, using an amyl alcohol standard, gives fair, though somewhat high, results in most cases.

With regard to the suggestion that "no artificial colour other than that derived from the wood in which it is stored is admitted in whisky," I am in thorough sympathy where this provision is intended to prevent the use of colouring matter employed to give a fictitious appearance of age. Sometimes, however, a small amount of colouring matter (caramel) is employed for the sole reason that the consumer will not buy a whisky that does not possess a certain standard of colour. To explain: in Scotland, the general method of imparting colour to whisky is storage in a sherry cask. As the consumption of whisky grew, it was found that there were not sufficient sherry casks obtainable for this purpose. The distiller, therefore, had to resort to the use of "plain" wood. Whisky stored in "plain" wood casks acquires very little colour as a rule, even after a number of years, and the result is that, although a spirit stored in this way may be quite as old and fine as that casked in sherry wood (apart from the distinctive sherry flavour), it cannot be sold unless it is brought up to the standard of colour demanded.

I am almost inclined to think that, under these conditions, the colouring, or part colouring, of the spirits with a harmless substance such as caramel can scarcely be considered to be an adulteration, and that it does not constitute "artificial colouring" in the practical sense of the term, any more than does the use of a charred cask. But I repeat that when colouring matter is added to a raw, neutral or cologne spirit, for the purpose of giving a fictitious appearance of age, then such colouring matter should be regarded as an adulteration, and that it should either be prohibited or be made subject to declaration. I would also point out that from an analytical point of view there is some danger that a perfectly genuine sherry cask coloured spirit might form the object of suspicion, inasmuch as the colouring matter of the sherry cask is apparently closely allied to some of the caramels of commerce, and that our tests for this class of bodies are by no means all that could be desired.

I think that the limitation of the solid matter to 0.25 per cent. will, on the whole, not interfere with the genuine whisky industry, but it may occasionally occur that a spirit stored in a cask that has contained a particularly heavy sherry might genuinely exceed this limit.

I venture to believe that the methods of analysis of whisky indicated by me in a former paper (*loc. cit.*) are likely to be of some practical value when a sufficient number of standard samples have been examined, and if the results be considered in connection with the opinion of an unprejudiced expert taster, and also, in case of doubt, with reference to such statements as to origin and manufacture as may be obtainable in any particular instance.

In conclusion, I wish to advert to one aspect of the pure food problem, particularly as it has a very practical bearing on the subject which has been treated in the above remarks. It has been suggested, both in England and here, that the solution of the food adulteration problem would be reached if every package were labelled with a detailed statement as to the exact nature of the contents, and the method of manufacture, and so on. I cannot help thinking that, in order that such a course should be successful, it would be necessary to make an expert chemist of every man, woman and child, otherwise such labelling, in my opinion, is only likely to lead to confusion and to cause serious injury to the manufacturers of superior articles. No one will venture to suggest that an article should not be correctly labelled, but I for one think it scarcely fair that full details in regard to the constituent parts and methods of manufacture should be published to the world at large. I take the liberty of suggesting an alternative method—a method that would secure perfect protection for the public, and at the same time would not possess the drawback of the detailed label. I suggest that every article of food or drink, either imported or manufactured at home, should, when first placed on the market, be submitted, together with a statement as to the origin, constituent parts, manufacture, &c., to a Board of Reference, composed of

* NOTE.—In some recent, and as yet, unpublished work by F. Kaye, A.R.C.S., and myself, we have been able to show that the mere "breaking down" (i.e., dilution) of brandy to the normal commercial lines, especially if effected with a very alkaline water, such as the excellent New River (London) water, is liable to seriously affect the ether value. This value so affected by the mixture of different brandies, the resulting ether value of the mixture being by no means equal to the arithmetical mean. We have found that "breaking down" with water such as that indicated, may reduce the ether value related to alcoholic strength in each case by more than 50 per cent. Under those conditions, a rigid legal ether standard will result in the condemnation of a perfectly genuine brandy.

† NOTE.—In connection with the 0.25 per cent. limit for solid matter, it is worthy of note that we have certain types of brandies in England to which small quantities of "sweet" are added. This is done with a view to producing a brandy of distinctive type and taste, and is not regarded in England as adulteration. I do not know whether these types are vendible here, but, if they are, possibly some modification might be made in the connection with the proposed standard of total solid matter where it is obvious that sweetening matter has not been added with a view to giving any fictitious value to the product.

‡ NOTE.—Per 100 c.c. absolute alcohol.

expert hygienists, chemists, and representatives of various industries. This Board should decide whether the article is wholesome, and whether it is honestly labelled. If the contents of the package are decided to be injurious, or misdescribed, then the article should be prohibited or referred back to the manufacturer. It passed, as being genuine, samples should be taken from time to time in the open market and submitted for examination to ascertain whether its quality is kept up to the original standard, due allowance, of course, being made for ordinary commercial variations of quality, which naturally may be considerable in the case of an article such as a wine or a spirit. The details as to an article's nature submitted to the Board suggested would not be published, but would be available in case of subsequent action.

A Board of Reference of the nature indicated, would, it given powers to set up standards and definitions, I believe, be of the very greatest assistance to those entrusted with the local execution of the general food laws.

Meeting held at Chemists' Club, on Friday, January 20th, 1905.

RUSSELL W. MOORE IN THE CHAIR.

PREPARATION OF VOLUMETRIC SOLUTIONS.

BY E. C. WORDEN AND JOHN MOTION.

The importance in volumetric analysis of solutions of easily determined accuracy, and the value of any observation tending to increase the facility with which such solutions may be prepared is, perhaps, a sufficient explanation for recording the following notes. These notes on the relation of specific gravity to composition were originally undertaken for sulphuric and hydrochloric acids and subsequently extended to oxalic acid, in order to obtain a delicate standard for the adjustment of permanganate, bichromate, thiosulphate, arsenite, sulphite, iodine, and other chemicals used in processes involving oxidation and reduction, because it had been felt that, in volumetric work, the methods of standardising the several solutions were often tedious, and not always satisfactory from the point of accuracy.

Higgins (*Ann. Jour. Pharm.*, 1901, 200; this J., 1900, 958) has discussed the several substances proposed as standards in acidimetry. Moody (*J. Chem. Soc.*, 1898, 658) and subsequently Higgins (*loc. cit.*) and Raschig (*Z. angew. Chem.*, 17, 577) have described a method of preparing an accurate standard acid, by passing gaseous hydrochloric acid into a definite volume of water and weighing the amount absorbed. This requires a rather delicate arrangement of somewhat complicated apparatus, but, when properly executed, is without doubt capable of great accuracy.

Compared with the above, the electrolysis of a solution of copper sulphate is somewhat simpler and more easily carried out. [Kohn (this J., 1900, 962), Meade (*J. Amer. Chem. Soc.*, 1901, 12), Danvé (this J., 1902, 1098).] On the other hand, it serves only as a basis from which the strength of other solutions may be determined, rather than for preparing actual solutions for use, as there is obviously a limitation to the quantity that can be conveniently prepared in this way.

Sørensen (*Z. anal. Chem.*, 42, 333) has investigated sodium oxalate, which, however, is inapplicable to acidimetry. Dietze has calculated the specific gravity of the preparations of the United States (*Pharm. Review*, 1897, 24; Merck's Report, 1897, 211; *Proc. Am. Pharm. Ass.*, 1897, 399), British (*Chem. and Drug*, 1897, 243), and German Pharmacopœas (*Phar. Zeit.*, 1897, 631), but the figures are limited to a definite concentration and the gravities extend to only three decimal places.

S. C. Pickering (*J. Chem. Soc.*, 1890, 64) has recorded a series of determinations of the density of sulphuric acid, considered by Richmond (this J., 1890, 479) "the

most complete ever published." He (Richmond, *Anal.*, 1892, 167) has compared Pickering's results with densities taken by himself, in which the sulphuric acid was standardised by three gravimetric barium sulphate determinations of 6-9 grms. of a solution containing 30 concentrated sulphuric acid per litre.

From the same source, Marshall (this J., 1899, 4, 10; 1902, 1552) deduces a formula whereby strong sulphuric acid is mixed with an equal volume of water, the density obtained, and the mixture diluted to a definite amount, the final adjustment being made by volume. Later (this J., 1902, 1508) he has investigated the influence of impurities on the specific gravity of sulphuric acid and published a table for each 0.001 in gravity.

The following notes on the relation of density to composition of sulphuric, hydrochloric and oxalic acids have been made only between those limits of strength which appear in the normal and deci-normal solutions of the three acids, and to furnish the data for the construction of tables VI., VII., and VIII. In the course of this work, covering a period of three years, we made upwards of 450 density observations at the temperature 15.56° C. (60° F.), with a corresponding number of gravimetric determinations. The oxalic acid investigation being extended at other temperatures and to its maximum solubility in water.

Purification of Chemicals.—The water was distilled from alkaline permanganate in a copper retort with a block tin condenser, then redistilled, the distillate condensed hot, and the first and last portions rejected each time. It had a very low electrical conductivity, and showed no evidence of the presence of ammonium compounds or of chlorides. Each chemical was examined, and exceeded in purity the standards as laid down by Krauch, "Testing of Chemical Reagents." They were from Kahlbaum, with the exception of the hydrochloric and sulphuric acids which were Merck's reagents, and the sublimed oxalic acid, which came from König. A semi-normal sodium hydroxide solution was prepared from metallic sodium purified by filtration through iron gauze in a vacuum, and this was gradually introduced in small pieces into recently boiled, distilled water, cooled to 2-4°, finally covering the solution with paraffin oil purified by repeated boiling with nitric acid.

It may be contended that it is difficult to procure acids of sufficient purity to give results of such accuracy. To test the importance of this point: (1) a portion of the sulphuric acid used was further purified by recrystallisations from a freezing mixture, decanting and discarding the mother liquor each time; and (2) comparing oxalic acid with the sublimed acid to recrystallised, and containing no trace of formic acid, and also that obtained from the hydrolysis of methyl oxalate of b. pt. 162.5° at 757 mm., and m. pt. 50°. No variation in the results was found.

Analytical Results.—Veley (this J., 1903, 1227) and others consider it "doubtful if volumetric methods can be carried beyond an accuracy of one part in 1000 parts, whereas density determinations can be carried to an accuracy of +1 part in 75,000 parts," and this can be extended to +1 part in 100,000 parts without difficulty where weighing bottles of large capacity are used.

Our work throughout was gravimetric, and as weighing was not counter-indicated, greater accuracy was sought by working on larger quantities than usual. For this reason, all determinations were taken with 100 c.c. pycnometer, a determination being understood to include a density observation, and the estimation of the contents of the pycnometer by precipitation. Each result, as subsequently given, comprises at least three determinations. In those instances where both of the worked independently on the same solution, at least twelve determinations are included in one result.

A sample of acid from three different sources was obtained, and used interchangeably throughout the work. They were precipitated as barium sulphate, silver chloride, and calcium oxalate respectively. The temperature of the solutions during filtration was not allowed to rise above 10° C., and in washing the precipitate, each portion of wash water was returned several times in order to reduce the volume used. It would appear from

ability determinations in water of silver chloride,* especially of barium sulphate,† that these precautions not without value.

The sulphuric acid was emptied from the pycnometer into a beaker, diluted with 250 c.c. of water for each gram. of dilute sulphuric acid present, the liquid brought to boil, and a 5 per cent. solution of barium chloride slowly sprayed with a fine atomiser into the boiling liquid with constant stirring, the addition requiring 25 minutes. The strength of the acid being determined beforehand by titration, there was added an excess of 2 per cent. of barium chloride over the theoretical amount required to form the sulphate. The hot solution cooled by immersion of the beaker in cold running water, the liquid decanted through a Gooch crucible and the filtrate returned. The precipitate after being washed with 25 c.c. of water for each gram. of sulphuric acid present, was transferred to the Gooch crucible, washed free from precipitant, and very gently ignited.‡ Lange and Isler (Z. angew. Chem., 1890, 129) have pointed out that in the sulphuric acid determinations Kolb (Dingl. Polyt. J., 204, 322), no account is given of any precautions observed.

The hydrochloric acid in 0.5 per cent. solution was precipitated in amber "Joliet" Erlenmeyer flasks, at 75°, with silver nitrate (containing 10 per cent. of nitric acid) in 5 per cent. excess. The flask was heated until the silver chloride had coagulated, leaving a supernatant liquid clear, then filtered through a Gooch crucible and dried to constant weight at 120° C. including the drying, which was done at night, the entire operation, which usually occupied less than six hours, was conducted under red light in a dark room, and in no instance was the chloride tinged with violet.

The oxalic acid was precipitated in a warm, slightly ammoniacal solution, reduced under the blast to constant weight and calculated as calcium oxide. Attempts to ignite the precipitate at 105° C. and weigh as the oxalate, to convert the oxalate into sulphate, did not yield concordant results in our hands. The loss of platinum during the several ignitions varied from 0.3—0.7 mgm. Ignition, the mean of the weights before and after, being taken as the true weight (Hulett & Berger, Amer. Chem. Soc., 26, 1512).

Density Methods.—On account of the low coefficient of expansion of the solutions (practically the same as water), and their non-hygroscopic character, the following method was adopted:—Two 100 c.c. Geissler pycnometers were obtained, the weight or capacity of which did not differ in each other by more than a fraction of a gram., the latter being used as a counterpoise. The external areas being nearly the same, the weighings are independent of barometric pressure, or the humidity of the air. They differed from the ordinary instruments in being provided with a capillary tube of but 0.2 mm. bore, and this tube is mounted by a ground glass cup, of about 30 c.c. capacity, the top being drawn to a capillary of less than 0.1 mm. external diameter. In absorbing the overflow with filter paper, the advantage of the small bore in over-

coming capillary attraction is evident, the object of the large cap with capillary opening being to relieve the pressure incident to expansion and contraction during weighing, without evaporation.

The pycnometer was filled with the acid solution at about 12° C., placed under a bell jar until the bubbles had arisen, the thermometer inserted and the whole immersed in water, which was constantly stirred during the rise in temperature. The thermometer was frequently tapped as in calorimetric work. The tare was taken before and at the end of each series of densities, and the mean of any variation accepted as the true weight. The capacity of the weighing bottle was adjusted by weighing water at each interval of one degree from 10.5°—19.5° inclusive. Three series of weighings, when plotted with weights as ordinates and temperature as abscissa, upon a scale of 1 mm. for 0.1° and 0.0001 gram., gave an extreme variation of 0.0005 at 15.56°. But two pycnometers were used throughout.

The temperature was recorded by an ordinary thermometer ground in the pycnometer and reading directly to 0.1°, and this was frequently compared with (1) a thermometer graduated in 0.1° and certified by the Reichsanstalt, (2) a standard Tonnellot thermometer at which the temperature 15.56° had been determined by the National (U.S.) Bureau of Standards. The temperatures are centigrade, and the calculations based upon the 1904 International Atomic Weights, with oxygen as 16. A Troemmer long arm balance was used, sensitive to 0.0001 gram., with a load of 200 gram. The brass weights were standardised among themselves, and the gram. weight adjusted by comparison with the standard at the National Bureau. All weighings were made by substitution, in the case of the Gooch crucible, a platinum tare being used.

The results obtained with the three acids are as follows:

TABLE I.

‡ Note on Sulphuric Acid.—The work involved some 225 determinations as barium sulphate, which afforded an opportunity of studying the method somewhat in detail, and operating on about 100 gram. quantities, slight variations became more apparent. Without exception, higher and discordant results followed, if a concentrated (15—20 per cent. solution) of barium chloride was used, or a more dilute solution added quickly, and also if the concentration of the sulphuric acid be much above 0.5 per cent.

The addition of the barium chloride by spraying was due to an endeavour to obtain a crystalline precipitate of larger grain, by slower formation of crystals, and also one which enclosed the minimum of barium chloride (Richards & Parker, Z. anorg. Chem., 413; Am. Acad. Sci., 31, 67). The method of Hulett & Duschalt (Z. anorg. Chem., 40, 196) of determining the "occluded" barium chloride by dissolving the barium sulphate in sulphuric acid, and aspirating the liberated hydrochloric acid into dilute silver nitrate as tried, but with negative results, thus indicating the sulphate to be free from all but inappreciable quantities of chlorides. The rate when allowed to remain at rest in tall beakers for several days, then filtered through a heavy layer of asbestos in a Gooch crucible, seldom gave as much as a mgm. of barium sulphate, an amount too small to affect the result.

The object in quickly cooling the hot solution is to induce convection currents in the liquid, thus causing the precipitate to sink and completely subside, and in doing so to take with it that fine "scum" of barium sulphate which floats on the surface, and is often in such a fine state of subdivision as to cause trouble in filtration.

No free hydrochloric acid was added, and no variation in the result or physical appearance of the precipitate was noted, when 1) 2 grms. hydrochloric acid was added for each gram. sulphuric acid present, (2) the hydrochloric acid came entirely from liberation in the interaction with the barium chloride (which is equivalent to 75 per cent. of the sulphuric acid originally present and 3) where a small amount of barium chloride was first added, then barium hydroxide, so that the total acidity did not exceed 15 per cent. of the sulphuric acid originally present. This differs somewhat from the experience of Richmond (Analyst, 1892, 167), who mentions that the solution must contain free hydrochloric acid in the proportion of at least 3 of hydrochloric acid to 1 of SO₃.

1.00532	101.2268	0.6850	1.514	8
1.00703	101.4583	0.9858	2.182	6
1.00775	101.4704	1.0075	2.220	9
1.00782	101.4774	1.0170	2.251	6
1.00800	101.4955	1.0363	2.293	6
1.01050	101.7479	1.3722	3.130	10
1.01591	102.2920	2.0966	4.590	6
1.01722	102.3240	2.2646	4.970	7
1.02177	102.8819	2.8883	6.305	6
1.02246	102.9518	2.9808	6.503	7
1.02450	103.1568	3.2702	7.126	5

In order to judge if the above figures represent results more accurate than the methods employed, it is to be remembered that with a 100 c.c. pycnometer, a variation of 0.0001 gm. in weight is required to affect the fifth decimal place in gravity, while with a solution of acid of (say) 5 per cent., a difference of 0.0252 gm. barium sulphate, 0.0436 gm. silver chloride, or 0.0465 gm. calcium oxalate is required to change the strength of the corresponding acid by 0.01 per cent. Most concordant results were obtained with the hydrochloric acid, where it was not unusual to obtain a series of six determinations with an extreme variation of not over 0.001 gm. The barium sulphate came next in point of accuracy, but the oxalic acid seldom varied more than 0.002 from the mean. These variations seldom affected the result by more than 0.001 per cent., and we believe it would not be unsafe to say that the 0.01 per cent. was established. No determination was left when the 0.005 per cent. was in doubt.

We append below a comparison of the figures of Pickering for sulphuric acid, as calculated by Marshall (this J., 1902, 1509), with our own:—

Sp. Gr.	Pickering.	W. and M.
	Per cent.	Per cent.
1.310	1.15	1.445
1.015	2.19	2.209
1.020	2.93	2.940
1.025	3.67	3.675
1.030	4.41	4.420
1.035	5.14	5.165
1.040	5.88	5.890

Marshall's figures are given for 15° C., in air, but would not appreciably affect the comparison. It was observed that the greatest difference in percentage value does not exceed 0.025 per cent., and that occurs at 5 per cent.

The specific gravity tables of hydrochloric acid of Lapeyrolle and Marchlewski (Z. angew. Chem., 1891, 133) and (Comptes rend., 74, 337), while, perhaps, correct for technical purposes, are not sufficiently concordant to be used as a basis for comparison with the present tables. The hydrochloric acid determinations of Pickering (26, 277) are for values higher than appear in our tables. In order to obtain indirectly a comparison of the results as recorded in Tables II. and III., with those of Pickering on sulphuric acid, and incidentally to determine the accuracy with which the above acids could be interchangably as in volumetric processes, a series of comparisons were made by titration.

A weighing bottle (see figure), which may not inappropriately be called a "gravimetric burette," was constructed of a capacity of 120—135 c.c. and weighing 35—40 gm. The side arm A, having an internal diameter of about 8 mm., ends in a ground stopper with a capillary perforation, as in an ordinary pycnometer. The opposite arm B contains a small one-way stop-cock, the end of the arm being enclosed in a ground cap E. The outlet beyond the stop-cock is constricted, so that the liquid may not reach the sides of the cap E. The capillary is to prevent evaporation, allowing the use of the instrument without removing the stopper. From several produced from the same batch of glass, three were selected of nearly the same weight and capacity, the lightest being used as counterpoise. It was found that a volumetric rapidity combined with a gravimetric accuracy could be thus attained, which greatly facilitated the work.

Solutions of sulphuric, hydrochloric and oxalic acids were prepared of about equal strengths, and six delicate determinations of each were made. A "burette" was filled with acid, 10—15 grms. weighed out, and titrated from another burette with a weighed quantity of sodium hydroxide, using phenolphthalein, Azolitmin, or Methyl Orange as indicator. Ten portions of the same acid were thus neutralised, and after weighing, placed in the same beakers so that any excess of alkali in one estimation might be accounted for in the subsequent one. The neutral solutions were then precipitated as the barium, calcium and silver salts as previously indicated and weighed. Therefore the strength of each solution was determined twice, first by titration, and subsequently by precipitation. The caustic soda solution was adjusted in a similar manner, by neutralising and precipitating ten portions of a 2 per cent. solution of hydrochloric acid using 20 gm. portions.

Five series of determinations with the three acids gave the following figures:—

TABLE IV.

Sulphuric Acid.				Hydrochloric Acid.			Oxalic Acid.		
No.	Sp. Gr.	Per cent. NaOH.	Per cent. H_2SO_4 .	Sp. Gr.	Per cent. NaOH.	Per cent. AgCl.	Sp. Gr.	Per cent. NaOH.	Per cent. CaO.
1	1.00784	1.124	1.126	1.00671	1.335	1.335	1.00372	1.068	1.068
2	1.01090	1.450	1.448	1.00745	1.483	1.484	1.00532	1.517	1.517
3	1.02444	3.610	3.609	1.01842	3.680	3.682	1.00775	2.218	2.222
4	1.03393	5.013	5.012	1.02474	4.962	4.963	1.01722	4.668	4.670
5	1.03923	5.779	5.782	1.02844	5.712	5.714	1.02177	6.207	6.207

It would appear from the specific gravity determinations of oxalic acid by Franz (J. prakt. Chem., [2] 5, 391) (Ann. Centralb., 1886, 769) and Gerlach (Fres. Zeit., 305), the authorities most frequently quoted in textbooks and works of reference, that additional observations are not be out of place. The specific gravity of crystallized oxalic acid as recorded by Franz (1932) for 12.6 per cent. strength, is less than that given by Gerlach (1937) for 10 per cent. strength, both being taken at 17.5°. Franz obtained his series of values from the titration of per cent., 10 per cent., and a saturated solution with normal sodium hydroxide.

Oxalic acid from four sources was procured, the sublimed acid recrystallised, and the oxalic ester hydrolysed. Specific gravity and strength were determined at about 10 per cent. and 6 per cent. concentrations. The methods used were: (1) titration with standard soda as above, (2) evaporation of the resulting sodium oxalate to dryness and weighing the same, (3) titration of the sodium oxalate with permanganate, (4) titration of the original solution with permanganate, (5) precipitating and weighing the calcium oxide, and (6) by evolution in a Geissler's carbonic acid apparatus, and leading the carbon dioxide into a wash bulb. The permanganate was standardised (a) as a "chemically pure" iron wire, in which the carbon had been determined by combustion, and (b) by ferrous ammonium sulphate, purified by 8 recrystallisations and analysed for iron, nitrogen and sulphur.

The results follow:—

STANDARD METHODS OF SAMPLING; REVIEW WITH SOME SUGGESTIONS.

BY MARTIN L. GRIFFIN.

My object in presenting some aspects of this subject in review in part what has been done during the past years, and to show from it how meagre the work has been, how very few valuable contributions have been made, to enforce the importance of correct sampling, and to offer a few suggestions.

The work on standard methods of analysis has received considerable attention of late, and the New York Section of the Society of Chemical Industry has made some very valuable contributions in this line. Standard methods of sampling, if it may not precede the analytical work, should at least go hand in hand with it. Its importance should not be overlooked or under-estimated.

About 20 years ago this subject was discussed at some length by several of the English sections of the Society of Chemical Industry. At that time the discussion was closed with that of standard methods of analysis, under the title International Methods of Sampling and Testing Commercial Products. The scope of the inquiry was so broad that it is no wonder that there was a wide divergence of views and no practical results. More would have been accomplished if only one reliable plan of sampling one commercial product had been recognised for individual

The discussion was started by Dr. Lunge making inquiries of prominent chemists and manufacturers in Germany, France and England. The answers were comparatively few and unsatisfactory. Less promise was given to methods of sampling than to uniform methods of analysis. Some declared the time was not opportune to approach so difficult a question, others that uniform methods of analysis were desirable, but could suggest no way to bring it about; but that anything like uniform methods of sampling was an impossibility, that sampling will have to be left to the intelligence of the sampler, or to the agents of the buyer or seller. However, sufficient interest was felt in the matter to cause the adoption of a resolution to appoint a committee to confer and discuss the subject further. The subject was further discussed at length by other sections a few months later, when many personal experiences in analytical work were detailed. Many facts were expressed that uniformity in practice by fixed rules would stifle improvement and original work, and that many trade usages and customs would be opposed to it. The idea seemed to be more or less current, also, that a coercive power was to be associated with the establishment of uniform methods, and it does appear that some moral obligation at least existed to use them, provided they could be established.

There seemed to be no bounds to the question; some advocated courts of appeal to settle differences between analysts reporting tests on the same sample of so simple a substance as soda ash.

As the discussion advanced, the advocates of uniform methods of sampling gained more prominence at the expense of uniform methods of analysis, and at this juncture Mr. Mellor gave as his contribution to the conference a method of sampling minerals. The discussion of his time closed with a resolution, endorsing standard methods of sampling ores, raw products and chemicals, with no reference whatever to uniform methods of analysis, leaving that, as one gentleman said, to take the course of the Darwinian law of the survival of the fittest.

At a subsequent discussion before another section, when many similar arguments were advanced, two incidents should be noted. John Miller declared, from his experience, that it was possible to sample accurately rich sulfiferous ores, and that the difficulty supposed to lie in sampling bolts of various kinds did not apply to the precious metals. John Hutchinson said in his experience of 10 or 12 years analysing samples of manures carefully drawn and apportioned to their different chemists, in case of discrepancy or difficulty with the results had occurred. If these gentlemen had then and there detailed their knowledge as to any peculiarities in the make-up

of cargoes of these goods and the method by which they were accustomed to be sampled, a nucleus from which to proceed would have been formed. It seems to me strange that the remarks of these two gentlemen should not have suggested a more rational and simple approach to the solution of the problem than the cumbersome and impracticable plan of passing resolutions to appoint committees to consider, and courts of appeal to judge. These men knew how to sample precious ores and manures, and they were competent to disclose a plan of sampling which would have been valuable to the trade and many young chemists, who must learn many things by trying experiences. The disposition of these gentlemen toward a helpful undertaking of the task was in marked contrast with that of him who advanced obstructive examples of the difficulties in sampling deliveries of fifty boxes of Italian olive oil soap, a few thousand boxes of Japanese fish oil, containing some water, a cargo of Spanish iron ore, varying in quality and size of lumps. He could have given a just and practical way of sampling these commodities, or else he should have welcomed this information from any reliable source, even by rules.

A little later, after having presented an excellent paper before the Liverpool Section on Methods of Sampling (this J., 1884, 339), Norman Tate, when asked how many casks in a lot of goods should be sampled, replied that when he had been able to draw samples from every single package, there had been no disputes. This was not a scientific answer, and leads to an absurdity. Suppose a lot of goods in casks or boxes were sub-divided and repacked to the practical limit without his knowledge, and he were asked to sample and test at intervals, would he employ the laborious method of sampling every single package? His answer implied that he did not, as a rule, sample every package, and that, therefore, he had had disputes.

Sampling is a matter of practical mathematics, of mean values, and the theory of errors, and may be accomplished on this line with accuracy. It does not even require discriminating intelligence, when once the plan of procedure is correctly determined.

The discussion at that time closed with a set of recommendations by the committee, the matter was dropped, so far as concerted action was concerned, and the records of the Society contain nothing of importance since.

The Association of Official Agricultural Chemists in the United States was organised about 1883, and had for its object the securing of uniformity and accuracy in the methods, results and modes of statements of analyses of fertilisers, soils, and cattle foods, dairy products and other materials connected with agricultural industry, &c. While uniformity in taking and preparing samples is not specifically stated, I think it is implied, and the results of the work of the association go to show that this has not been neglected, though not receiving the attention which it deserves. An examination of their published records on methods of analysis reveals some directions as to how samples should be taken, and rather more on the preparation of the sample for analysis. They have learned to their sorrow how much depends upon the preparation of their sample for concordant results, especially in fertiliser and soil analysis. If they had been called upon to test the commercial worth of their services individually to the fertiliser trade, by each man drawing his own samples from a cargo of raw stock, the matter of sampling would have been vigorously dealt with at once. On the contrary, the Association has given itself up very largely to the determination of how concordant results may be reached when one uniform sample has been divided and distributed among several chemists. This is extremely important, but no matter how accurately the analytical work may be performed, if the sample is not representative, the results are worthless.

The results of the Association's work are almost entirely summed up in the bulletins, "Methods of Analysis," and whatever conclusions we draw from the contents of these will represent the work it has done on the subject of sampling. I find this covers the sampling of butter, cheese and soils. The recommendations for sampling butter and cheese are not of much value, scientifically; in the case of cheese, they are open to criticism (Bulletin

No. 46, revised). The alternate methods there detailed are not in harmony. The sampling of soils has, apparently, engaged their attention to a much greater degree, and quite lengthy instructions are given in the bulletin referred to.

At the seventeenth annual convention, Dr. B. Dyer, of London, made a forcible plea for uniform methods of sampling soils. On motion, this was referred to the referee on soils. At the next convention the referee offered several criticisms of Dr. Dyer's method, and suggested placing the matter in the hands of a committee. At the same convention, Mr. C. G. Hopkins submitted a method of soil sampling which was finally adopted as a provisional method.

The referee for the following year, in sending out instructions how to sample to other chemists, who were to co-operate in the work, paid no attention to this provisional method, though he gave his own very explicit instructions. No further reference to this subject has appeared.

Dr. H. W. Wiley, chief chemist of the Department of Agriculture, in his work, "Principles and Practice of Agricultural Analysis, 1895," has described at length the principal methods of soil sampling at home and abroad, but does not summarise their essential features. To the taking of samples of fertilisers he has devoted one short paragraph, which might just as well have been omitted. The more difficult and impractical it is to give directions as to the drawing of samples of any particular commodity, the greater the reason for pointing out what the peculiar difficulties are. To say that generally the samples which are brought to the chemist, have been taken without his advice or direction, and he is simply called upon to make an analysis of them, is not a happy disposition of a question in which the chemist must share some responsibility.

I have reviewed this matter here in some detail to show the exact position of a body of exclusively Government chemists organised for the purpose of promoting uniformity in their class of work. It seems to me this subject is one of the first which should have engaged their attention, and that they have unfairly spent their time on other things to the detriment of this which involves their whole work. It is not enough to give a plan of sampling one cheese, one tub of butter, or the soil of a few pots of oats.

As an illustration of the need of a shrewd, careful, and experienced knowledge in drawing samples, the Department of Agriculture of the State of New York, not long since, had a case against a milk dealer in New York city. The Department's inspector had sampled the milk from the various cans as it was received by the dealer at the station. Milk not up to the legal standard was found, and a case entered against the dealer. At the trial counsel for the defence admitted the correctness of the samples as taken, and the accuracy of the analyses, but demurred that the samples were improperly taken and did not represent the product his client sold, in that he mixed his milk before delivery, and that such milk had not been sampled at all. The case was dismissed.

In this connection I will refer to a case cited recently in the "Analyst" (London), which is the only reference I find in their published records on samples or sampling.

The case was this. A Government agent purchased from a small shopkeeper six two-ounce bottles of camphorated oil, all bearing the same label, and apparently the same in all particulars. He divided them up into three lots of two bottles each without opening, mixing or dividing the contents of any, and sealed each separate lot. One of these he delivered to the respondent, another to the analyst, and the third he kept. The analyst found his sample did not meet the test required by the Government. The appellant contended that he had complied with the Food and Drug Act in the division of the sample. The justices thought differently, and were not satisfied that the two bottles analysed by the analyst were identical in nature and substance with the other two sets. They accordingly dismissed the summons. On appeal, their lordships held that this was a purchase of six separate articles, and dismissed the case.

In looking over the work of chemists in the American Chemical Society, I find two important papers pertaining to sampling. The first—"Some Experiments on Sampling

by Quartation," Vol. XV. The object of the experiment detailed by the authors was to determine the degree of accuracy obtainable by quartation, as well as to discover the best way of mixing. The authors have in mind sampling of ores. They prepared a mixture of equal parts of lead shot of one size, magnetic iron ore of another and crushed glass of still another size. After repeated mixing and quart-er-ing, they determined the relative proportions, and from many experiments finally drew useful conclusions.

In Vol. XIX, we find a most excellent paper by Edwin Keller on the Distribution of the Precious Metals and Impurities in Copper and Suggestions for a Ratio Mode of Sampling. His paper deals at length with the behaviour of these elements in copper when changed from a molten to a solid state. A large number of samples from different portions of the pig were drawn and analysed, and from these results he draws valuable conclusions as to how the whole operation of sampling should be done.

Such information as this must be very helpful to chemists who are engaged in this kind of work, and who may not have had the requisite experience. These two papers comprise all that has been contributed to this Society in 25 years. It is not much, but still a very creditable contribution.

Turning to the Transactions of the American Institute of Mining Engineers since its organisation over thirty years ago, I find two valuable scientific papers dealing with general principles of ore sampling, and one of special application. The first of these will be found in Vol. X, Sampling Ores without the Use of Machinery, by W. Glenn. Regarding the importance of sampling, Mr. Glenn says—"There is no metallurgical or chemical establishment which does not frequently receive samples representing nothing. The work of sampling is overlooked upon as within the realm of boys and pensioners only. At least, though the manual labour be left to subordinates, the principles on which it is conducted are the safeguards with which it is surrounded are unworthy of the study of experts; and experts should be ready to teach these principles and enforce them in practice. Expert sampling is the indispensable first step toward learning the value of any boxful, car-load or shipload of ore."

Mr. Glenn's method rests essentially upon a mathematical basis, a plan of drawing the first rough sample, the crushing and quartering to final sample. He says, and truly—"It does not matter in the slightest what solid a sample may consist, or how much or how little it may be, it should be worked down in the manner detailed." By this he means, of course, this underlying principle must be the framework, and the details to be suited to the particular case. Machine sampling may be more practical when possible as at the mines and smelters, but it must rest upon the principles here detailed. This paper is a valuable contribution to the subject. Vol. XXV, of the Transactions, Mr. D. W. Brunton has a paper on The Theory and Practice of Ore Sampling. He says—"The object of the investigations and experiments here recorded was to obtain such information as data as would make it possible to determine the finer details to which crushing must be carried, in sampling gold and silver ores, in order to obtain results within an allowable limit of error." His work is graphically illustrated to determine these limits mathematically, and the same plan may be applied to determine the allowable limits for other ores and materials which must be crushed and sifted or screened in the preparation of a representative sample. He shows the importance of re-crushing after each successive "cutting down," so that as the sample diminishes in weight, there may be a nearly constant ratio between the weight of the sample and that of the largest particle of ore contained therein.

The last reference in the Transactions is that of a paper by Mr. C. M. Roberts, Vol. XXVIII.—Experiments in the Sampling of Silver-lead Bullion. The work detailed in this paper is similar in character to that of Mr. Keller, described above. He states that his "series of tests were conducted to establish the fact that there is no regularity in the distribution of the silver inside the bar, but that the

rt of the bar which lies directly against the sides of the
dd is the richest;" he also shows how reliable samples
y be taken.

Having now reviewed at some length how the subject
s been regarded and what has been done to the present
e, we can see how many things have been accomplished
hich once seemed impracticable.

Many standard methods of analysis have been worked
t and are recognised to-day. We do not need to attach
y coercive influence to use any standard method.
s do not need to stamp any such method with the seal
the Society, or with any authority except the plain
ts upon which the methods rest. These constitute their
e claim to recognition. Not long since, Dr. R. W.
ymond, Secy. of the American Institute of Mining
gineers, said in effect, that the Institute gave no warrant
to the truth or accuracy of statements made by its
mbers in their publications contained in the *Transac-*
ions, but that it was coming to be so well understood
t the *Transactions* were so reliable as to constitute them
authority upon the subjects with which they dealt,
is it seems to me is the true test of authority.

The Association of Official Agricultural Chemists have
mployed the rational plan of dealing with this subject,
has selected a number of its own qualified chemists to
estigate and report upon a particular subject, and has
n eliminated all the defects and probable errors as far
possible.

Very valuable work has been done on many subjects of
e, including proximate analyses of coals, cements, and
nent making materials, and still other subjects are being
estigated. The question of drawing and preparing
iable samples involves no such amount of research as is
ecessary for the analytical work, but a knowledge of how
do it is extremely important and a similar method of
cedure may be followed. I would suggest that a few
emists working along the same lines undertake to dis-
cuss directions how samples of raw materials with which
y are familiar should be drawn. Indeed, if chemists
ividually would contribute what they know from
eir own individual experience, it would be very sugges-
e and helpful oftentimes.

Another question closely allied to this is—How many
ples shall be drawn from a cargo of goods in barrels,
les, or separate packages, in order to get a true repre-
entative sample? Upon this question, I have already
pared something which I trust will prove valuable,
d I expect to present at this session.

MR. S. F. BURFORD IN THE CHAIR.

TANKS FOR CARRYING TAR AND GAS LIQUOR BY RAIL.

BY F. J. R. CARULLA.

There are four interests involved in the construction of
railway tank wagon, viz. :—

1. That of the railway company.
2. That of the gas company selling the tar and liquor.
3. That of the maker of the tank wagon ; and
4. That of the chemical manufacturer or owner of the
agon.

The first three interests are so powerful that the owner
practically effaced as regards the construction of the
hicle.

The railway company over whose line the wagon has to
avel is concerned with the proper construction of the
ader carriage, and that the tank shall be strong enough
o carry a quantity not exceeding 10 tons of tar or liquor,
eing quite indifferent as to the shape of the tank. For
me not very obvious reason the railway companies
bject to tanks of larger capacity than 10 tons.

The gas company selling the tar and liquor really decides
the shape of the tank. To meet the convenience of the
gas company the shape of the tank may have to be that
of a parallelogram instead of the possibly more eco-
nomical and certainly stronger form of a cylinder. Small
gas works inconveniently situated frequently send their
liquid residuals to be loaded in petroleum barrels, which
are lifted to the top of the railway tank and emptied into
it. In this case the roof of the tank has to serve as a floor
on which the barrels are rolled so that the flat form becomes
indispensable.

The maker of the tank naturally gives the lightest
structure consistent with the requirements of the railway
company, and the owner or chemical manufacturer will
feel quite satisfied that he has done his best by getting the
cheapest tank that the railway company will pass.

Now, the railway company is not concerned with the
construction of the tank itself, although it carefully
examines the tank. Steel plates are very strong, even
when thin, and a tank made from $\frac{1}{8}$ -in. plates will last
many years without leaking.

A time is sure to come, however, when the tank begins
to give trouble on account of its construction, and it is
then that the chemical manufacturer or owner awakes
to his real interest in the matter.

Any loss through leakage he has to pay for, and the
railway company immediately asks the owner to have the
tank repaired. The maker of the tank wagon patches
the tank up and thus gives it a further lease of life.

What the cause for the necessity of such a repair in a
flat tank may be was most instructively illustrated not
long ago by one that leaked in several places at the bottom,
and which, on examination, was found to require renewal
practically all round the seating. The plates forming
the bottom of the tank were taken out, and some 9 or
10 in. sheared off all round, and narrow plates rivetted
on, forming a frame for the middle of the old bottom,
which was quite sound and almost of the original thickness
everywhere except at the edges.

How this came about will readily be understood from
the fact that the iron or steel bottom of a flat tank rests
on the wooden frame of the wagon body, and, however
strongly stayed together the two portions of the com-
bined structure may be, a certain amount of abrasion is
constantly going on whenever the wagon is in motion,
which rubs off any protective coating in contact with the
wood exposing the metal to oxidation. The rust thus
formed becomes imbedded in the wood, which, when the
vehicle is in motion, acts as an emery stick, so that in the
case referred to through this action the bottom of the tank
was in many places not more than $\frac{1}{8}$ th of an inch thick at
the edges.

The object of the present note is to suggest to chemical
manufacturers that when ordering new tank wagons they
should specify the addition of what may be called an
abrasion strip to be rivetted to the tank to take up this
wear in all those places in which the plates come in contact
with wood, and to be attached in such a manner that when
worn out such strips may be easily renewed.

The owner will then find that at the cost of a few
shillings he has nearly doubled the life of the tank.

DISCUSSION.

MR. J. F. KEMPSON said that Mr. Carulla's method might
prevent a certain amount of wear at the angle of the tank,
but he doubted whether it would be of any very great
value. A flat-bottomed tank, settled down on a good
wooden framework, lasted a long time. He had had one
or two tanks running for considerably over 16 years, and
they were not bad ones yet. He detailed a form of setting
for flat tanks, which they had found satisfactory. At each
end of the tank a strong baulk is placed on edge, going from
one side to the other of the wagon frame, to which the two
baulks are securely fastened. The frame with these
baulks across it form a cradle to hold the tank in its place,
and, with the tie rods of proper strength, there is very
little of the wear referred to in the paper.

MR. CARULLA approved of the form of setting described,
but thought that even in that case the abrasion strips he
advocated would be an improvement.

Meeting held at Derby, on Wednesday, January 25, 1905.

MR. S. F. BURFORD IN THE CHAIR.

EFFECT OF SULPHUR ON SILICIOUS PIG IRON.

BY G. J. WARD AND A. H. LONGDEN.

Mr. O. F. HUDSON, in his paper on the "Glazing of certain kinds of Silicious Pig Iron and its Causes" (this J., 1904, 595-598), draws the following conclusions:

(1) The glazing of certain kinds of silicious iron is caused principally by an increase in the percentage of sulphur.

(2) The difference is the appearance of the fractures is due to the small size of the graphite plates in the case of glazed iron.

It is somewhat doubtful if sulphur is always present in high proportions in glazed pig iron.

For instance, two analyses of Stanton "glazed" pig iron give sulphur, 0.033 and 0.046 per cent., and silicon, 5.13 and 4.50 per cent. Assuming that glazed pig iron does contain high percentage sulphur, then it follows that either (1), the glazing is due to sulphur, or (2), the glazing and the sulphur are due to the same cause.

If (1) is true the addition of sulphur to pig iron containing high percentage silicon should give "glazed" iron.

To test this, about 112 lb. of molten metal were put in each of two clean hand ladles. Test bars were made with the metal, and the molten metal was also treated with a weighed quantity of iron sulphide and mixed well, and test bars were run from the alloy.

Any of the alloy which was not required for the test bars was run into a small pig; by the analysis of this pig it could be seen if the sulphur had been mixed up.

The quality of the iron was especially noted in the pig bed at the time the two ladles were taken from the furnace. Thus, from the above we had three different specimens of iron from each experiment, *i.e.*, two sets of test bars 36 in. by 2 in. by 1 in., and a small pig of the sulphur alloy. The name "sulphur alloy" will be given throughout this paper to the pig run from the spare metal after running the test bars.

Experiment 1.— $\frac{1}{2}$ lb. iron sulphide was added to the molten pig iron, which was of a good grey No. 1 quality, and mixed in with a carbon rod; test bars were then poured from the alloy. The fracture of the "sulphur alloy" was light coloured.

Experiment 2.—In this experiment and the remaining experiments, the iron sulphide was put into the ladle before adding the molten metal, as it was found to mix better than by adding the iron sulphide to the molten metal; $\frac{1}{2}$ lb. of iron sulphide was put into the ladle, and the molten metal added; the quality of the iron run in the pig bed was glazed in part of the cast, and No. 2 iron in the other part.

Experiment 3.—2 lb. of iron sulphide was put into the ladle and the molten metal added; the quality of the iron run in the pig bed was good open No. 3 iron. This was mixed with an iron bar covered with slag and test bars poured from the alloy; these bars drilled very hard indeed. The fracture of the "sulphur alloy" was light coloured and "blowhole" in one end of the pig.

Experiment 4.—1 lb. of iron sulphide was put into the ladle and the molten metal added. The quality of the iron run in the pig bed was over-grey, fracture No. 3 iron, but not a satisfactory iron. These cast iron test bars drilled harder than all the other test bars, and the fractures of all the bars looked as if some small dirt had got into them. The alloy test bars drilled rather soft, and also looked to have got a little dirt into them.

The fracture of the sulphur alloy was good No. 3 iron and "blowhole" in one end of the pig; the best colour as regards "sulphur alloy pig" good grey.

In none of these experiments with an iron fairly high in silicon could we produce a glazed iron by addition of sulphur, consequently if it be true that "glazed" always contains high sulphur this must be because the same cause which produces glazing in the iron tends also to increase the sulphur.

Wedding, in his standard book on Iron, page 171, s "it seems certain that free silica, where accompan by no other mineral which can form slag with it, suc calcium carbonate, tends to the production of iron rich silicon, especially where the temperature is very h and there is much carbon present."

Glazed iron is made where the temperature of the bi is high, there is an excess of fuel, and where the furnac working on an acid slag. There is undoubtedly a tenden for the sulphur to get into the iron where the slag acid, and these high sulphurs are in our opinion due the same cause as the glazing, and not the glazing due the extra sulphur.

Turner (Metallurgy, page 198) expresses the opin that the bright crystals in glazed iron are silicides carbon or of iron.

Carnot and Gontal (this J., 1898, 1150) said silicious ir containing little manganese treated with 5 per cent. c sulphuric acid leave a residue which consists of carb silicon hydroxide, and different combinations of iron i silicon. The hydroxides of iron and silicon are remov by potassium hydroxide. The manganese and iron removed by sulphuric acid. The residue contains 19 to 19.86 per cent. of silicon and 79.63 to 79.84 per ce of iron; this corresponds to SiFe_2 . This was a co pound prepared by Moissan in an electric furnace, i thus prepared it consisted of glittering scales.

It is probable that the glazing of iron is due to presence of this SiFe_2 produced by high temperature the presence of an acid slag, and that under these c ditions there may be a tendency for the sulphur to u with the molten pig iron.

DISCUSSION.

Mr. O. F. HUDSON considered the results of the exp ments of great interest, especially as showing the influ a small increase of sulphur has upon the fracture of c iron. With reference to the author's failure to glaze i by the addition of sulphur, he pointed out that glaz only occurred when the silicon was over 3.5 per ce and was not commonly seen when it was much bel 4 per cent. From the analyses given of the remelted i it was seen that the silicon varied from 3.15 per cent. a maximum of 3.52 per cent. It could, therefore, har be expected that such irons would be glazed. The fract of the irons remelted with addition of sulphur was, in majority of cases, light coloured, a change in the direct of glazing, and pointing, no doubt, to graphite of a sma size. It would have been interesting to have had ful details of the composition of the iron used.

He gathered that the high blast temperature and a slag, the conditions under which glazed iron is made w suggested as being in themselves the cause of glazi It seemed more probable that those conditions o indirectly caused glazing by favouring an increase of sulpi in the iron, and that an open grey silicious iron of suite composition could be glazed outside the furnace by addition of sulphur.

With reference to the presence of the compound SiFe_2 in the free state in cast iron, Carnot and Gontal in a m

ent paper* than the one quoted by the authors, stated that although ferrosilicons contain both SiFe and SiFe_2 , they had been unable to isolate silicides of iron from ordinary cast iron. Moreover, during the repeated microscopic examination of glazed iron no indication had been obtained of the presence of a free silicide of iron, the other hand, it was very probable that silicon yielded an important part in giving a glazed fracture, so iron containing upwards of 4 per cent. of silicon in solution (in which condition silicon doubtless existed in cast iron) was easily fractured, the fractured crystals presenting bright shining surfaces. Therefore, given a cast iron, with the necessary amount of silicon and with all graphite, the fracture would pass through the silicite as easily as along the graphite, and, indeed, it is just to a large extent so; hence its light-coloured, flaking appearance.

Mr. L. ARCHBUTT said the silicon in the irons under observation was not exceptionally high. He suggested at further experiments should be made on pig irons attaining higher percentages of silicon.

Mr. J. O'SULLIVAN said that boiled sulphur and silica, when mixed together, set very hard, and he had even tried that this mixture was used in fastening studs in walls.

Dr. R. M. CAVES was under the impression that Mr. Hudson previously said it was an increase of sulphur which caused glazing; now he was inclined to say it was iron.

Mr. G. J. WARD said that before he made the test he would want to know how much silicon he would need in the iron. He thought that Mr. Hudson's remarks about SiFe_2 bore out what he (Mr. Ward) had already said, about 4 per cent. of silicon there was a sudden change in the iron which was not accounted for by the elementary analysis, and this was probably due to the fact that the substance which up to that point had been present as a solid in solution was changed into the silicide. It was hardly possible that the addition of 2 per cent. of ferrous sulphide would alter the nature of the iron. From 3½ to 4 per cent. of silicon must be present. The point was that iron with this quantity was sometimes glazed and sometimes not, and there was nothing in the analysis to show any difference. Mr. Hudson's argument was that 0.05 per cent. of the addition of sulphur was the cause of glazing; it seemed more likely that some change in the SiFe_2 , which formed the 20 per cent. of the pig iron, could result in this complete alteration in the character of the iron. He agreed with Mr. Archbutt that it would be more conclusive if further tests were made with the iron containing more silicon. The difficulty was that as the samples were taken immediately from the blast furnace, it was impossible to tell the percentage of silicon till after the experiments were made. The breaking strains given, though good for an iron containing so much silicon, were lower than would be obtained from a harder iron, say No. 4.

Meeting held at Derby on Wednesday, January 25th, 1905.

MR. S. F. BURFORD IN THE CHAIR.

MINERAL CONSTITUENTS OF SUMACH AND ITS ADULTERANTS.

BY M. C. LAMB.

The writer, having for several years been particularly interested in sumach and its more common adulterants, has read with a considerable amount of interest the paper communicated to the Nottingham Section of the Society by Mr. Trotman on "The Mineral Constituents of Sumach."

The writer can confirm from personal experience the results of the analyses of the ash of samples of commercial sumach given by Mr. Trotman, and his remarks as to the

want of care evidently taken by the sumach grinder in carrying out the winnowing process, as shown by the high percentage of mineral matter usually found.

A sample of pure sumach leaf (*Rhus Cotinifolia*) was found to contain: Fleishy substance of leaves, 72.5 per cent.; leaf stems (mid rib, &c.), 6.6 per cent.; stalks, 20.9 per cent.

This sample was one obtained from a grower by a disinterested person, and shows the relatively large proportion of leaf stalks contained in the sample as sold to the grinder, and which are presumably all ground up with the leaves.

Ash determinations of the above gave the following results:—Fleishy substance of leaves, 6.3 per cent.; leaf stems (mid rib, &c.), 8.1 per cent.; stalks, 3.9 per cent. The sample as a whole gave 5.89 per cent. ash.

The above are chiefly remarkable for the very small amount of ash found in the stalks, and the large percentage given by the leaf stems (mid rib, &c.).

Ash determinations made upon leaves of the two most common adulterants of sumach, *Pistacia Lentiscus* and *Tamarix Africana*, are interesting on account of the large amount found in the latter. The average amount of ash found in two different samples of *Tamarix* and three samples of *Pistacia* (all these samples being in the unground form) were 10.6 per cent. and 4.8 per cent. respectively. The average percentage of ash found in three samples of ground *Tamarix* was 10 per cent., and in three samples of ground *Pistacia Lentiscus* 6.8 per cent.

DISCUSSION.

Mr. S. R. TROTMAN said that Mr. Lamb's paper appeared to bear out the remarks which he made at the last meeting, when he suggested that 6.5 per cent. should be an outside limit for the ash of sumach. He had further received a communication from A. A. Barrett, of Messina, who mentioned that the grinder usually stipulated for not more than 5 per cent., or occasionally 7 per cent., of sand and stones. If this were so, it was evident that the ash given by Mr. Lamb for ground leaf, namely, 5.89 per cent., should be easily attained. There was no doubt that this question would shortly become important, as adulteration was very prevalent.

Mr. JAMES O'SULLIVAN inquired if the chlorides and sulphates were given in the analysis of the ash of sumach. It was his experience that the sulphate and chloride found in the ash of plants was no index to the quantity present, since the process of ashing destroyed these constituents. This was more noticeable if magnesium sulphate was also present. He believed that the determinations of ash of plants, so far as the chlorine and sulphuric acid present in the plants were concerned, were worth nothing.

Scottish Section.

Meeting held at Glasgow on Tuesday, January 31st, 1905.

MR. G. H. GEMMELL IN THE CHAIR.

THE DETERMINATION OF SMALL PROPORTIONS OF BROMINE AND CHLORINE IN IODINE.

BY R. R. TATLOCK AND R. T. THOMSON.

The method we propose is a gravimetric one, which we have used for several years, and is the result of an inquiry and investigation made with the object of determining bromine and chlorine in commercial iodine. We examined many of the processes recommended, but were unable to obtain one which was sufficiently accurate, and, as there is still a demand for a good method, we have thought it desirable that this should be put on record. In recent text books there are methods given for the determination of bromine in presence of iodine, but small quantities (0.5 gm.) of the sample are operated upon, as the iodine is liberated and boiled off, which is troublesome

* Annales des Mines, Oct., 1900; Metallographist, Oct., 1901.

and disagreeable, especially if large quantities are treated. Now, the detection and estimation of small percentages (from, say, 0.1 to 1.0 per cent.) of bromine in such small quantities of sample is not at all satisfactory, and, therefore, we have adopted the plan described below.

From 5 to 10 grms. of the sample are treated with 50 to 100 c.c. of water, and a finely granulated or in the form of dust is added in small quantities at a time, with frequent agitation, until the iodine is all converted into the iodide. Great care must be taken not to allow the temperature to rise to any sensible extent which would cause the zinc were added too rapidly. The solution is then filtered, the insoluble portion washed two or three times, and finally 3-5 grms. of pure sodium nitrite added if 5 grms. of the sample have been operated upon, and 7 grms. if 10 grms. have been employed. The mixture is next carefully acidified with diluted sulphuric acid, when the iodine is all liberated according to the well-known reaction, and is nearly all precipitated. If the precautions referred to are taken, no bromine is liberated, and this can only take place if the solution becomes strongly acid and is, owing to the careless addition of strong sulphuric acid in place of the diluted acid. The precipitated iodine is removed by filtration, washed two or three times with cold water, and the filtrate treated in a separator with benzene, which will remove the small proportions of iodine left in solution. The lower layer is run off into another separator, a little more sodium nitrite and sulphuric acid added in case there should be any traces of iodine still left, and the mixture again shaken up with benzene. If benzene happens not to be available, either chloroform or carbon bisulphide may be used to remove the iodine, and any of the solvents may be purified for further use by shaking up in a separator with zinc dust and water.

If thought necessary the solution may be heated to expel any traces of the solvent, and the bromine and chlorine precipitated as the silver compounds by adding silver nitrate in excess, and then adding some nitric acid, and heating to boiling. The silver salts are now collected on a weighed filter, and washed well with hot water, the filtrate and washings being of no further use. In order to remove the silver chloride a solution containing 2 grms. of silver nitrate, 90 c.c. of water, and 10 c.c. of ammonia of 0.880 sp. gr. is prepared. About 60 c.c. of this solution are poured backwards and forwards through the filter containing the precipitate, and the latter washed with the remaining 40 c.c. of ammoniacal silver nitrate. We have found that by this treatment any silver chloride derived from chlorine present even in much larger proportion than is usually the case in commercial iodine, is easily dissolved out, and the silver bromide is left perfectly insoluble. The latter should now be washed with dilute warm nitric acid, then with hot water, dried and weighed. The ammoniacal solution is next acidified with nitric acid, heated, and the silver chloride precipitate collected as usual.

The only other point that is necessary to attend to in the identification of the silver bromide precipitate, is the application of a test which will show that there is no iodide left in it. The test we have found most convenient is as follows:—The precipitate is treated with dilute sulphuric acid and zinc dust until decomposition is complete, then filtered, a limited quantity of chlorine water added to the filtrate, and the mixture shaken up with a small quantity of carbon bisulphide or chloroform. If iodine present a violet tint will be communicated to the solvent but if bromine only the colour will be reddish-brown.

There is no necessity to give figures proving the accuracy of the method, but we may just state that we have not used the process for about ten years with the most satisfactory results.

Obituary.

CARL OTTO WEBER, Ph.D.

MEMBER OF THE SOCIETY OF CHEMICAL INDUSTRY.

Carl Otto Weber was born in Pforzheim, South Germany, October 26th, 1860, and was partly of German and partly of Scottish extraction. He studied chemistry at Heidelberg, and under Fehling at Zürich, receiving his Doctor of Philosophy degree at Heidelberg in 1880. He became engaged in the pigment colour industry, and rose to take the management of a large chemical factory in Silesia. In 1892 he went into the manufacture of india rubber, and became chemist at the Greengate Rubber Works, Salford, Manchester. He also acted as abstractor for this Journal, principally for the subjects of indiarubber and gutta-percha during a period of about ten years. By extensive researches in the peculiarly difficult field of the chemistry of indiarubber, Dr. Weber at length obtained recognition throughout Europe and America, as one of the foremost authorities on the subject, a position confirmed by the publication of his work on "India Rubber and its Analysis" (this J., 1903, 51). Two years ago he went to America, and at the time of his death acted as consulting chemist to the Hood Rubber Company, as well as to several other firms representing the same industry. Shortly before this he had made an extensive study on the spot of the methods employed in obtaining and curing rubber in Central America, and he then proposed important improvements in those branches, as well as in the difficult subject of rubber analysis. Dr. Weber was also associated with Messrs. Cross and Bevan in collaboration on the subject of cellulose acetate and the problem of solid emulsions of cellulose and rubber. He was a man of wide reading, and also of considerable repute as a musician. He died suddenly from heart failure, on Saturday evening, January 14th.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—8d. each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—1s. each, to the Secretary of the Society.

French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs-Bourgeois, Paris (3^e).

I.—PLANT, APPARATUS, MACHINERY.

ENGLISH PATENTS.

parators; Centrifugal Liquid —. J. H. F. Dieck, and C. J. Möllmann, Osnabrück, Germany. Eng. Pat. 16,855, Aug. 2, 1904.

U.S. Pat. 778,406 of 1904; this J., 1905, 123.—T. F. B.

ating or Vaporising Water or other Fluid; Apparatus for —. B. W. Davis, Phillips, Wis., U.S.A. Eng. Pat. 25,966, Nov. 29, 1904.

U.S. Pat. 777,083 of 1904; this J., 1905, 77.—T. F. B.

UNITED STATES PATENTS.

parator; Centrifugal —. C. J. Pihl, Cambridgeport, Mass., Assignor to United States Dairy Manufacturing and Machine Co., Kittery, Me. U.S. Pat. 780,141, Jan. 17, 1905.

ROTATING bowl has an inner unperforated wall. The ed-pipe passes through the centre of the inner body, from which radial wings project into the annular space between the inner and outer walls. The liquid to be separated passes as a thin film of slight "radial depth," through the vertical annular passage, which is situated in the field of greatest centrifugal force, so that the particles have only a short horizontal distance to travel in order to be separated.—W. H. C.

vaporating and Distilling Liquids; Apparatus for —. B. F. Brooke-Sewell, Skien, Norway. U.S. Pat. 781,045, Jan. 31, 1905.

Two or more vessels, with bottoms formed of a series of pockets with inclined sides are arranged one above the other. The vapours rising from the liquid contained in the lowest vessel condense on the under surface of the pockets of the vessel next above, giving up their heat to them and collecting in a trough placed below the pockets. The liquid to be evaporated can be passed from one vessel to another by suitable pipes, and the solids deposited during the evaporation can be withdrawn, without breaking the vacuum, which is maintained in the apparatus.

—W. H. C.

II.—FUEL, GAS, LIGHT.

Smoke and Volatile Matter yielded by Coals; Determination, in a Platinum Crucible, of the Percentage of —. G. Arth. XXIII., page 212.

ENGLISH PATENTS.

Peat and Peat Charcoal; Apparatus for the Production of Dry —. G. T. Zohrab, Glasgow. Eng. Pat. 1628, Jan. 22, 1904.

THE peat is placed in a suitable receptacle, and conveyed by means of an endless band provided with knives or blades, to a plate heated by gas. Above the hot plate are arranged a number of endless bands mounted on rollers so as to incline downwards towards the rear end of the hot plate. These bands are fitted with knives, the peat being carried along to the end of the hot plate, and any moisture squeezed out in transit. The heated peat is then delivered into a number of hoppers, from which it falls into the pulping cylinders. Inside these cylinders are arranged Archimedean screws and knives mounted on rotating shafts, as well as stationary knives, by which means the peat is cut up, kneaded, pressed forward and on through a mould on to trays. While on the trays it is cut up by suitable apparatus, and the trays are then conveyed to drying chambers. A blowing and exhausting apparatus for forcing air of any desired temperature into the drying chambers, is provided.

After drying, the peat blocks are discharged, and may be conveyed to, and charred in a retort, and afterwards cooled by jets of steam in a cooling chamber. —L. F. G.

Peat Fuel; Apparatus for the Manufacture of —. J. MacGregor and G. C. Pearson, Old Charlton, Kent. Eng. Pat. 2268, Jan. 29, 1904.

THE claim is for apparatus suitable for carrying out the process described in Eng. Pat. 19,719 of 1902 (this J., 1903, 943). The peat is charged through a hopper into the basket of a centrifugal machine, which has a sliding contact electrode on its periphery, and another situated in the interior of the basket. The latter expands or extends under the influence of the centrifugal force, and so maintains electrical contact with the peat as it shrinks. From the centrifugal, the peat, when deprived of its superfluous water, is delivered into a kneading trough, provided with blades which reduce it to a suitable state of plasticity for forming into blocks. The peat is then turned out into the hoppers of the moulding machine, where by means of rams or plungers, actuated by a "rotating cam groove," it is forced into the moulds, and eventually expelled on to a conveyor.—W. H. C.

Briquettes; Manufacture of —, for Fuel and other Purposes. W. Simpkin, Westminster, and J. B. Ballantine, Richmond, Surrey. Eng. Pat. 14,213, June 23, 1904.

BLOOD is mixed with a solution of potassium nitrate, about 15–20 lb. of nitrate being taken per ton of blood. Instead of potassium nitrate, carbonates and acetates of the alkalis, or weak acids, may be used to prevent coagulation. 100 to 200 lb. of the treated blood are then mixed with a ton of powdered coal, to which are also added 10 lb. of powdered rosin for every 100 lb. of blood used. The mixture is then formed into briquettes, and heated in an oven for a suitable time to 250° F. If extra strong briquettes are desired, 20 to 30 lb. of slaked lime may be added to every ton of coal used.—L. F. G.

Fuel; Artificial Composition —, and Process of Producing same. C. H. Carpenter and S. L. Davis, South Bend, Ind., U.S.A. Eng. Pat. 24,336, Nov. 10, 1904.

1950 lb. of dried common peat, decayed vegetable matter or soil, are mixed with 10 lb. of common salt, and 40 lb. of powdered rosin. The mixture is then compressed into briquettes, a pressure of 24,000 lb. per sq. in. being used to properly distribute and retain the rosin throughout the mass.—L. F. G.

Liquid Fuel; Use of —, and Apparatus for Burning the same. Sir W. G. Armstrong, Whitworth & Co., Ltd., E. L. Orde, and W. H. Sodeau, Newcastle-on-Tyne. Eng. Pat. 3089, Feb. 8, 1904.

THE steam or hot air spray burner described in Eng. Pat. 23,568 of 1899 (this J., 1900, 1004) is combined with a mixing chamber. The apparatus is so designed that sufficient air, amounting to not less than four times the weight of the oil, may be drawn in and intimately mixed with the oil spray before the mixture ignites, so that a practically smokeless flame is produced. This is attained by constructing the mixing tube so that the "suction-plane" is in advance of the inlet for the induced current of air, and by extending the mixing tube into the furnace.

—W. H. C.

Liquid Fuel; Burning of —. J. Badger, Harlesden, Middlesex. Eng. Pat. 5218, Mar. 2, 1904.

THE liquid fuel is fed into the conical tube *a*, of refractory material, which in turn projects into an annular, regenerative track *b*, built of segmental bricks *c*, which are formed with a falling arch *q* in order to reduce the size of the outlet. The inner wall of the track is formed by the upright tube *d*, and a layer of broken refractory material *e*, introduced through the flanges *f*, is placed on the bottom of the track. A coil *h*, which serves for preheating the water or superheating the steam, also helps to support the inner edges of the bricks, sufficient space being left for the passage of the gases. A

pipe or jet *j* passes through the perforated bottom plate *i*, and serves to introduce the secondary supply of air.

—W. H. C.

Gas Producers. J. B. Smith, Glasgow, and R. Grant, Wishaw, Scotland. Eng. Pat. 5535, March 7, 1904.

WITHIN the combustion chamber of a rectangular producer there is provided a bridge of arched cross-section, extending from the front to the back of the chamber at some distance above the floor, for the purpose of supporting the fuel, so that it may form an arch extending from one side wall to the other, the side portions being unsupported. The arrangement is such that a clear central raking run is formed below the bridge, and made accessible to the raking and poking irons from the front end of the chamber. The bridge may be provided with apertures to allow steam, or steam and air, to pass up through it from a pipe extending beneath it.—H. B.

Gas Producers. B. Talbot, Leeds, and L. Mond, London. Eng. Pat. 6719, March 19, 1904.

A GAS producer, having the general form of shell and grate described in Eng. Pat. 12,440 of 1893 (this J., 1894, 938), and stirring arms and central blast, as described in Eng. Pat. 10,019 of 1900, is provided with separate blast-inlets for the central blast and the circular grate, so that the air, or mixture of air and steam, may enter partly through the grate and partly through the central blast in any desired proportions. Stirring arms may be arranged in the fuel bell, as well as in the main body of the producer.—H. B.

Air Gas; Process and Apparatus for Generating — [from Hydrocarbons, Alcohol, &c.], E. Gersabeck, Berlin. Eng. Pat. 14,355, June 25, 1904.

SEE Fr. Pat. 344,205 of 1904; this J., 1904, 1082.—T. F. B.

Filaments for Electric Lamps; Machines for Treating — The British Thomson-Houston Co., Ltd., London. From General Electric Co., Schenectady, U.S.A. Eng. Pat. 2456, Feb. 1, 1904.

THE machine is designed for the automatic "flashing" of carbon filaments, and comprises a number of "flashing" bottles, each of which in succession is, by means of an automatically operated valve, placed in connection first with a vacuum pump, whereby air is withdrawn, then with a measuring vessel from which it receives a predetermined charge of "flashing vapour," and, lastly, with the atmosphere, to remove the remainder of the vapour.

For safety, the vapour supply is drawn from a reservoir distant from the machine. The circuit through filaments is made, and broken when the resistance reached a predetermined value, by means of automatic switches. The starting of one operation in one bottle causes other operations of the cycle to be performed on the other bottles.—H. B.

Incandescence Bodies for Electric Incandescence Lamps; Process for the Formation of [Osmium] — W. Thompson, London. From Deutsche Gasglühlicht-A.G. (Auer Ges.), Berlin. Eng. Pat. 27,713, Dec. 1904.

INCANDESCENCE filaments which are brittle in the cold, especially those of metallic osmium, are brought to the desired shape by heating them to incandescence with electric current in an indifferent atmosphere, and bend them whilst in the softened state. For example, an osmium filament is laid across, or attached to, two terminals inside a vertical tubular vessel, which is open at the bottom for the insertion of the necessary instrument and at the top is closed with the exception of an inlet for hydrogen gas. A gentle stream of hydrogen, flowing down the tubular vessel, prevents the ingress of air at the bottom. The filament is raised to incandescence and then is bent to the desired shape by pushing suitably formed wires, or by raising the frame, carrying the terminals and filament, until the latter presses against a fixed stop and is bent as desired.—H. B.

Arc Light Electrodes and Methods of Making the same — C. F. Lindsay, Schenectady, U.S.A. Eng. Pat. 26,999, Dec. 9, 1904. Under Internat. Conv., Dec. 10, 1904.

ELECTRODES, suitable for giving a steady flaming arc, are made from a partially reduced mixture of oxides of iron and titanium. For example, 70 parts of magnetic oxide of iron, 30 parts of rutile, and 1 part of potassium carbonate are ground together and mixed with 10 parts of coke, and heated in crucibles to about 1200°. The partially reduced mixture obtained is ground moistened with glycerin and water, and moulded, squirted into pencils or the like; the pencils are dried in coke, and again fired at about 1200° C.—H. B.

Cement for Use in Electric Lamps and for other Purposes; Manufacture of — Cleminson Electric Lamp Attachment, Ltd., and W. King. Eng. Pat. 660, Mar. 18, 1904. IX., page 198.

UNITED STATES PATENTS.

Heating Composition. E. Kafka, Assignor to Firelight Heating Co., New York. U.S. Pat. 780,352, Jan. 1, 1905.

THE claim is for a mixture of about 25 per cent. of lead acetate, 50 per cent. of sodium sulphate, and 25 per cent. of sodium acetate, for the purpose of retaining and gradually emitting heat.—W. H. C.

Coke; Electrical Apparatus for Separating — from Cinders, &c. H. Lelarge, Liege, Belgium. U.S. Pat. 781,437, Jan. 31, 1905.

SEE Eng. Pat. 5799 of 1904; this J., 1904, 653.—T. F. B.

Gas Producing Apparatus. R. S. Craig, Chicago. U.S. Pat. 780,026, Jan. 17, 1905.

A GAS-PRODUCER, provided at the top with a feed hopper for solid fuel, and an inlet pipe for hydrocarbon vapour is connected to a fixing chamber and then in its turn and at its bottom part with the bottom part of a second fixing chamber, from which second chamber the gas passes down through a receptacle comprising (1) at its top, a vaporising chamber within which depends a coiled pipe serving to vaporise the hydrocarbon on its way to the producer; (2) a vertical tubular condenser to which air and water are admitted; and (3) at the foot a collecting box. The hot air from the condenser is passed into the producer beneath the grate-bars.—H. B.

Generating Furnace. J. H. Foster, New York. U.S. Pat. 781,141, Jan. 31, 1905.

FURNACE chamber, having double walls, is provided in lower portion with a horizontal partition, extending from the front to the back of the chamber, but leaving spaces at the sides which communicate with air ducts beneath the partition. A "burner or retort," supported on the horizontal partition, extends from the front to the back of the chamber; it consists of a shell, having closed ends, and provided with side apertures, and an inlet tube extending into the shell from the front end to a point near the rear end thereof.—H. B.

Gas and Coke from Crude Oil; Method of Manufacturing — J. H. C. Stut, Oakland, Cal. U.S. Pat. 81,242, Jan. 31, 1905.

Oven, having a layer of incombustible porous material at the bottom, and a relatively large empty space above, is heated, and crude oil is sprayed in a horizontal direction into the space in such manner as to prevent its clinging upon the walls or upon the porous material. The heat is sufficient only to separate the more volatile portions of the oil, which pass off as illuminating gas. The heavier portions fall upon the porous bed. In succeeding heating period air is admitted above and below the porous bed, consuming the lighter hydrocarbons, converting the deposited residue into coke. The making and coking operations succeed one another alternately. (Compare U.S. Pat. 766,554; this J., 1904, 124.)—H. B.

Illuminating Gas; Process of Manufacturing — J. C. H. Stut, Oakland, Cal. U.S. Pat. 781,380, Jan. 31, 1905.

AL, contained in several contiguous ovens, is raised incandescence; fresh coal is added to a higher level of certain of the ovens, and, whilst the coal-gas is disengaging off from the fresh coal, oil is introduced upon the incandescent surface of the fuel in the intervening ovens, and simultaneously steam is passed up through the fuel in the latter ovens. The mixture of water-gas and oil from the latter mingles with the coal-gas from the former ovens, and is led through a fixing chamber. The ovens are used alternately for producing coal-gas, and a mixture of oil- and water-gas.—H. B.

Ethylene; Process of Treating — for Facilitating its Transportation and Storage. E. A. le Sueur, Ottawa, Canada. U.S. Pat. 781,009, Jan. 31, 1905.

ETHYLENE is obtained in a form convenient for transit, condensing it, by refrigeration at atmospheric pressure, in liquid or solid form, or it may be "condensed into solution" in a suitable solvent by refrigeration. It may subsequently transferred to a storage receiver, which maintained at a comparatively high temperature, or may be admitted to a receiver containing a liquid or solid absorbent for acetylene.—T. F. B.

FRENCH PATENTS.

Agglutinant; Agglomerant or — for the Manufacture of Briquettes. D. Elis. Fr. Pat. 346,675 Sept. 30, 1904.

THE agglutinant is prepared by working up paper with cold or cold water, and finally boiling the mixture so as to form a paste. This paste or pulp is then mixed with al, charcoal, wood shavings, coke dust, or similar materials, and the mixture formed into briquettes and dried.—L. F. G.

Alcohol for Heating, Lighting, or Motive Purposes; Treatment of Carburetted or Non-carburetted — H. Rosalt. Fr. Pat. 346,606, Sept. 27, 1904.

SATURATED alcohol of any kind, or alcohol carburetted with benzene, benzene, petroleum ether, turpentine, or terpenes, is treated with ammonia gas, to prevent or neutralise acidity in the products of combustion. Instead of ammonia gas, the weak compounds of ammonia with ethyl, methyl, and especially amyl alcohol, may be

used, as also ammonium carbonate, methyl and ethylamine, or the distillation products from beetroot molasses.—L. F. G.

Gas Retort (Continuously Fed). J. Verdier and P. Toulon. First Addition, dated Sept. 8, 1904, to Fr. Pat. 335,004, Sept. 2, 1903. (See this J., 1904, 1081).

INSTEAD of the continuous rotary movement of the charging and discharging plugs mentioned in the principal patent, each plug is caused to rotate or oscillate alternately from right to left, and left to right. One charging hopper may be connected to shoots leading to two retorts, the oscillating plug delivering the fuel to each shoot alternately. The discharging plugs are provided with two cavities, placed symmetrically on opposite sides of the axis, instead of with one, so as to be balanced better. H. B.

Gas for Motive Power; Apparatus for the Manufacture of — A. Saurer. Fr. Pat. 346,526, Sept. 10, 1904.

THE apparatus consists of a gas-generator for the combustible (anthracite, coal, coke, lignite or liquid fuel) lined with refractory material, and provided at the top with a tubular heater, closed by a valve. The generator is surrounded by two concentric hollow cylinders, forming two annular spaces, closed at the top and bottom. Air enters through an opening and passes up the outer annular space, whilst the Dowson gas produced in the generator, when the apparatus is working, passes down the inner annular space, and to the motor. The air is heated in its passage, and passes through a pipe into the tubular heater, and then downwards into the bottom of the generator. The admission of the air is controlled by a valve. Water drops through a tube into the tubular heater, becomes vaporised, and mixes with the air supplied to the generator. The amount of water supplied is accurately regulated by means of a suitable thermo-regulator actuating a cock, and a Dowson gas of uniform composition is thus produced, the high temperature obtained inside the generator making it very rich in hydrogen.—L. F. G.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

Petroleum from Boryslaw; Determination of Impurities in Crude — M. Wielezyski. XXIII., page 212.

Mineral Oils; Determining the Flashing Point of — W. Herbig. XXIII., page 212.

ENGLISH PATENT.

Anthracene; Process for Obtaining Pure — from Crude Anthracene. V. Vesely and E. Votocek, Prague, Bohemia. Eng. Pat. 27,596, Dec. 17, 1904.

CONCENTRATED sulphuric acid is found to extract the whole of the basic impurities from a solution of crude anthracene in a solvent immiscible with sulphuric acid. The most suitable solvents are mineral and coal tar oils but carbon bisulphide or chloroform may be used. For example, 100 parts of crude (35 per cent.) anthracene are dissolved in 300 parts of solvent naphtha, 100 parts of concentrated sulphuric acid are added, and the mixture is heated and at the same time vigorously agitated for a few minutes. The sulphuric acid having been drawn off the solution is freed from acid by agitation with calcium carbonate, filtered, and allowed to crystallise. By this process it is stated to be possible to obtain an 85 to 90 per cent. anthracene, perfectly free from carbazole.—T. F. B.

UNITED STATES PATENT.

Asphaltic Oils; Method of Rendering — more "Limpid." E. A. Starke, Alameda, Cal. U.S. Pat. 781,240, Jan. 31, 1905.

HEAVY mineral oils are rendered more "liquid" and "limpid" by subjecting them to a partial distillation at a

temperature of 500–650° F., so that the residue is not coked. The distillate and residue are then mixed together.

—T. F. B.

FRENCH PATENT

Petroleum, Solidification of —, V. E. F. Bruhl. Fr. Pat. 346,619, Sept. 29, 1904.

PETROLEUM may be solidified by incorporating with it either 3 to 10 per cent. of soap, or 3 to 6 per cent. of soap and 1 per cent. of wax. —T. F. B.

IV.—COLOURING MATTERS AND DYE STUFFS.

Quinone Di-imine of —, R. Willstaetter and A. Pfannenstiel. Ber. 1904, 37, 4605–4609.

QUINONE DI-IMINE previously obtained (this J., 1904, 542) by reduction of quinone-dichlorodi-imine with hydrochloric acid, may also be prepared by oxidation of *p*-phenylenediamine with silver oxide in ethereal solution. The same reaction applied to *p*-aminophenol leads to the formation of quinone-mono-imine which cannot be obtained by the reduction method.

The mono-imine is less stable than the di-imine, readily soluble in ether, benzene and carbon bisulphide, and insoluble in petroleum ether. Both the mono- and di-imine are colourless. Comparison of these compounds with quinone and fulvene, proves that the groups C:NH have a weaker chromophoric power than C=O and C=C groups, which is contrary to the view usually adopted. Graebes imino-formula for the auramine salts, becomes also less probable. —R. L.

*Dimethylaniline-*p*-sulphonic Acid and new Azo Dye stuffs prepared from it*. L. Lefevre. Rev. Gen. Mat. Col. 1905, 9, 35.

DIMETHYLANILINE-*p*-SULPHONIC acid can be prepared by heating dimethylaniline at 100° C. with six times its weight of fuming sulphuric acid (containing 50 per cent. of sulphur trioxide). It combines with tetrazobenzidine forming a substantive dyestuff which dyes cotton a reddish-bordeaux. If only a single molecule of the acid be taken, an intermediate product is formed which gives off nitrogen on boiling and acquires a yellowish-brown colour. This dyes cotton direct in dark yellow shades. —A. B. S.

Azo Dye stuffs from Phenetol; New —, L. Lefevre. Rev. Gen. Mat. Col., 1905, 9, 35–36.

CONTRARY to the usual opinion that phenolic ethers do not combine readily with diazo compounds, it is found that phenetol unites with tetrazobenzidine to form an insoluble dyestuff, which dyes cotton direct from an aqueous-alcoholic solution. By using phenetol-*p*-sulphonic acid, a soluble dyestuff is produced which dyes cotton direct an orange yellow. Direct dyestuffs are also produced by combining one molecule of tetrazobenzidine with one molecule of dimethylaniline-*p*-sulphonic acid and one molecule of phenetol or of phenetol-*p*-sulphonic acid. —A. B. S.

Nitrosophenol Dye stuffs. H. Döcker and B. Solomina. Ber. 1905, 38, 64–68.

THYMOL methyl ether and crude nitric acid react in acetic acid solution to form a dark blue liquid. On reduction with stannous chloride and hydrochloric acid this is decolorised with formation of the hydrochloride of dithymolamine of the dimethyl ether [(CH₃)₂C(CH₃)C₆H₂·2NH]. On oxidation in alcoholic solution with ferric chloride, this forms the red methyl ether of thymoquinone-thymolide (C₃H₇)(CH₃)(O)C₆H₂N·C₆H₂(CH₃)(C₃H₇)(OCH₃). This is reduced by stannous chloride to the leuco compound dithymolaminemethyl ether HO·C₁₀N₂·NH·C₁₀H₂·OCH₃. Purified thymoquinone-thymolide obtained from thymol and sulphuric acid containing nitrous acid (Ber. 1903, 36, 2886) is converted by means of dimethyl sulphate in alkaline solution into the above-mentioned thymoquinone-thymolide methyl

ether. The *n*-butyl ether of thymol yields with concentrated nitric acid in acetic acid solution bronze-coloured crystals of the formula C₂₂H₃₂O₉N₃ which are quite analogous chemical behaviour to the product obtained from the ethyl ether of thymol. On reduction it forms the dibutyl ether of dithymolamine, which yields on oxidation the *n*-butyl ether of thymoquinone-thymolide. Analogous products are obtained from the isopropyl ether of thymol and from the methyl and ethyl ethers of *p*-xylenol. —E.

Malachite Green and Crystal Violet. R. Lambrecht and H. Weil. Ber. 1905, 38, 270–282.

WEAKLY acid alcoholic solutions of both Malachite Green and Crystal Violet yield with hydrogen sulphide and with alkali sulphides and polysulphides colorless solutions containing the carbothiols HS·C(C₆H₄N(CH₃)₂)₂ and HS·C(C₆H₄N(CH₃)₂)₃. On warming with excess of dilute acetic acid or with theoretical amount of dilute sulphuric acid, hydro-sulphide is evolved and the ordinary quinonoid salts the original dyestuffs are formed. With excess of mineral acids, on the other hand, no hydrogen sulphide is evolved and the solutions remain colourless, even when warmed for some time on the water-bath. They contain the carbothiol hydrochlorides HS·C(C₆H₄N(CH₃)₂·HCl)₂ and HS·C(C₆H₄N(CH₃)₂·HCl)₃, which can be isolated in the form of double salts with stannic chloride. On heating the dried salts, or boiling in aqueous solution the ordinary quinonoid salts of the original dyestuffs are formed with evolution of hydrogen sulphide. Analogous colorless salts of the carbinols of the dyestuffs, HO·C(C₆H₄N(CH₃)₂·HCl)₂ and HO·C(C₆H₄N(CH₃)₂·HCl)₃ can be isolated from solutions of excess of mineral acid as double salts with stannic chloride. On boiling the carbothiol or carbinol salts from either dyestuff with excess of mineral acid, deep-orange-yellow solutions are obtained from which orange-red double salts can be isolated with stannic chloride. They correspond to the formulae—

The authors further succeeded in obtaining, in the form of a zinc chloride double salt, a grass-green salt of Crystal Violet, of the formula—

In view of the stability towards oxidising agents of the carbothiols, they suggest formulae for carbothiols and carbinols derived from—

—E. F.

Alizarin Dimethyl Ether. C. Graebe. Ber. 1905, 38, 152–153.

ALIZARIN cannot be directly converted into its dimethyl ether, nor have purpurins containing two hydroxyl groups in the 1:2 positions been hitherto completely methylated. By reducing alizarin to desoxyalazarin, methylating the latter with dimethyl sulphate in alkaline solution, and oxidising the resulting product with sodium chromate and acetic acid, alizarin dimethyl ether is obtained and forms golden-yellow needles. The product is identical with that obtained by Meister, Lucius and Brünning from 2-hydroxyanthraquinone, by converting it first into 1-nitromethoxyanthraquinone and boiling this product with a solution of potassium hydroxide in methyl alcohol. By direct methylation of flavylium purpurin a dimethyl ether was obtained, whilst reducing, methylating and oxidising, as described above, flavylium purpurin trimethyl ether was prepared. —E. F.

New Vat Dye stuffs of the Anthracene Series. O. Baer. Ber. 1905, 38, 194–196.

By the action of glycerin on 3-aminoanthraquinone in the presence of a dehydrating agent, the reaction does not

on the formation of a quinoline derivative, but a molecule of glycerin enters into the reaction. The product crystallises from toluene in yellow needles, melting at 251°C .; it has the composition $\text{C}_{20}\text{H}_{11}\text{ON}$. It is apparently formed by the condensation of one molecule of β -aminoanthraquinone with two molecules of glycerin, thus—

The same product is formed by heating Gräbe's anthraquinoline with glycerin, so that the second molecule of glycerin must have reacted with a ketone oxygen to form a new ring, the "benzanthrone" ring. By heating anthraquinone with glycerin in sulphuric acid solution, the simplest representative of this new class of bodies is

formed, namely, benzanthrone, $\text{C}_{17}\text{H}_{10}\text{O}$ or , m.p.

17°C . A number of these bodies on melting with caustic alkalis form vat-dyestuffs of great fastness. The blue stuff Cyananthrene is formed in this manner from anthrone-quinoline. This is the first case of a compound which does not contain nitrogen, behaving as a "t" dyestuff.—A. B. S.

ENGLISH PATENTS.

Nitro-derivatives of certain Aromatic Bases [Arylsulphonides]; Manufacture of the —. C. D. Abel, London. Rom. Act.-Ges. f. Anilinfabrikation, Berlin. Eng. Pat. 141, March 19, 1904.

Ar. SULPHAMIDES obtained by condensing benzenesulphoxide or *p*-toluenesulphochloride with primary or secondary aromatic amines, may be converted into mononitro compounds having the nitro group in the *p*-position to the sulphamino group, by nitrating with dilute nitric acid (e.g., of sp. gr. 1.18), with or without the use of a solvent. The nitro derivatives of *p*-toluenesulpho-*o*-aniside, benzenesulpho-*o*-aniside, *p*-toluenesulpho-ethylamide, *p*-toluenesulpho-anilide and *p*-toluenesulpho-*o*-toluidide are described. These compounds may be reduced to the corresponding amino-derivatives, which are suitable for the production of dyestuffs, or they may be converted into nitro-amino compounds by the action of concentrated sulphuric acid, which splits the arylsulpho-group.—T. F. B.

Aracene Dyestuffs suitable for Dyeing and Printing; Manufacture of —. H. E. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 7692, March 31, 1904.

See Fr. Pat. 343,608 of 1904; this J., 1904, 1026.—T. F. B.

UNITED STATES PATENT.

Aligo; Process of Purifying —. R. Hutzler, Assignor to Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. U.S. Pat. 750,886, Jan. 24, 1905. See Eng. Pat. 7395 of 1903; this J., 1904, 248.—T. F. B.

—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

Woolen Materials; Scouring of Milled — by the aid of Electricity (Baudot's Process). E. Justin-Mueller. Soc. Ind. de Rouen, Dec. 16, 1904. Chem.-Zeit., 1905, 29, 102—103.

A milled cloth is passed in the open width through a tank divided into several compartments and fitted with rollers. The compartments in the first portion of the apparatus contain a solution of sodium carbonate (3°T) and are also provided with electrodes by which an electric current is passed through the liquid.

The remaining divisions are filled with hot water. The action appears to be as follows:—The electric current decomposes the sodium carbonate, forming caustic soda and carbon dioxide. The caustic soda facilitates the removal of the soap from the material and also saponifies any oil present in the state of an emulsion in the soap. The carbon dioxide decomposes the liberated soap and sets free the oleine which rises to the surface and is removed. The same action is repeated continuously. The bath is kept at about 40°C ., and the process is said to be very rapid.—A. B. S.

Parantrauline Red on Cotton Yarn. L. Sander. Z. Farben- u. Textil-Ind., 1905, 4, 13—14.

To avoid the difficulties usually experienced with diazotising baths, the use of stable diazo compounds such as Azophor Red has been largely tried. The yarn must first be well boiled out, preferably under pressure. For 50 kilos. of yarn, 2 litres of caustic soda (66°T) are required. The boiling is continued for 4 hours, and the yarn is then washed well, dried and treated with a solution of naphthol in alkali. Twelve litres of the naphthol solution as given below are taken and 1 kilo. of yarn worked in it, the duration of treatment depending on the tightness of the twist, &c., of the yarn. For each further 1 kilo., $\frac{2}{3}$ litre of the naphthol solution is added. The yarn is dried at 50° — 60°C . without too much exposure to light. After cooling, it is treated in a similar manner in 1 kilo. portions in the Azophor Red developing bath. This consists of $7\frac{1}{2}$ litres of Azophor Red solution (see below), 11 $\frac{1}{2}$ litres of cold water, and 1 $\frac{1}{2}$ litres of dextrin solution (1:3). Each further 1 kilo. of yarn requires the addition of $\frac{3}{4}$ litre of the Azophor Red solution. After squeezing, the yarn is left for 1 hour and then soaped for $\frac{1}{2}$ hour at 40° — 50°C . with 2 $\frac{1}{2}$ kilos. of soft soap and 200 grms. of soda ash, for 50 kilos. of yarn. It is finally washed. To make the shade bluer it may be topped with Rhodamine B.

Naphthol Solution.—Dissolve 1110 grms. of Naphthol R. in 12 litres of boiling water and 2.25 kilos. of caustic soda (36°T). Also dissolve 3.33 kilos. of Turkey Red oil (60°O) in 31.25 litres of warm water and enough caustic soda to give a clear solution. Mix the two solutions and make up to 50 litres.

Azophor Red Developer.—Stir 3715 grms. of Azophor Red P.X. with 22 litres of cold water, allow to stand 1 hour and filter through a cloth, washing the residue on the cloth with 9 litres of cold water. To the clear solution add slowly, with constant stirring 1960 grms. of caustic soda (36°T) diluted with 5 litres of cold water. Then add $5\frac{1}{4}$ litres of dextrin solution (1:3), allow to stand 10 minutes before using. The shade on bleached yarn is brighter than that on unbleached.—A. B. S.

Diamine Dyestuffs Printed on Cotton; Fixing —, by Moist Steam. E. Justin-Mueller. Rev. Gen. Mat. Col., 1905, 9, 36—38.

If the direct cotton dyestuffs be steamed in the dry condition after printing, they do not develop well and are not so fast to washing as the dyed colours. To remedy this, the pieces should be damped before steaming by wrapping in damp cloths or by any other suitable method, and glycerin should be added to the printing colour so as to attract moisture. The resulting colours are better developed and faster to washing.—A. B. S.

ENGLISH PATENTS.

Animal Fibres; Bleaching of —. T. Graham and F. Cope, Dewsbury, Yorks. Eng. Pat., 8851, April 18, 1904.

Zinc powder (56 parts) are mixed with sodium bisulphite (1000 parts) and, after settling, the liquid is drawn off. Barium chloride (10 parts) are added to the solution and the material is soaked in this for $\frac{1}{2}$ —3 hours at 100°F . It is then washed with tepid water and treated with a solution of potassium permanganate (1:1000), washed and dried. Instead of barium chloride, calcium sulphate, magnesium sulphate, aluminium sulphate, or alum may be employed.—A. B. S.

Vegetable Fibres. Mordanting for Direct Printing. (with Direct Printing). The Calico Printers' Assoc., Ltd., Manchester, and W. Warr, Staleybridge, Lancs., Eng. Pat. 25,165, Nov. 19, 1904.

THE material is first padded with a solution of a mordant salt, such as magnesium sulphate. The strength of the solution is varied according to the depth of colour required. The material is then dried and the magnesium fixed on the material as by lixide by means of a solution of caustic soda. The mordant may also be fixed as silicate by using a solution of sodium silicate. After washing, the material is ready for dyeing or printing with the substantive dyestuffs. A. B. S.

Printing, Mordanting, Bleaching, and the like Materials in Bobbin or like form. L. Petre, Reims, France. Eng. Pat. 47,577, Feb. 26, 1904.

THE machine consists of a suitable tank fitted with a number of hollow vertical columns or supports, preferably of triangular section. On the vertical faces of these supports are placed a number of horizontal receptacles B

to contain the bobbins. The end A is formed by the perforated face of the support; the cover C, which is secured by bolts d, is also perforated. Through the centre passes a tube a of special construction (see Eng. Pat. 45,964 of 1904; this J., 1904, 487). The hollow supports are connected to a pipe, and by means of a pressure or exhaust pump, the dye-liquor contained in the tank can be circulated through the bobbins in either direction.—A. B. S.

Tube for use in Dyeing, Bleaching, and the like Operations. J. Brandwood, Elton, Lancs. Eng. Pat. 6456, March 17, 1904.

SEE Fr. Pat. 342,109 of 1904; this J., 1904, 899.—T. F. B.

Hydrosulphite Compounds [with Ketones]; Manufacture of Stable —. O. Imray, London. From Farbwerke vorm. Meister, Lucius und Brüning, Höchst on the Maine, Germany. Eng. Pat. 6216, March 14, 1904.

STABLE compounds of hydrosulphites and ketones are obtained by the reaction of the two substances in presence of alkalis, especially caustic soda and ammonia together. A solution of the acetone-hydrosulphite compound is obtained by adding 1 part of acetone, 1 part of caustic soda lye (40° B.), and 1 part of 35 per cent. ammonia solution to 10 parts of a 13 per cent. solution of sodium hydrosulphite. By evaporating the solution *in vacuo* at a low temperature, the compound is obtained in solid form, in which it is very stable. These compounds are suitable for use in printing, particularly in the processes

described in Eng. Pats. 13,116 of 1903 (this J., 1904, 1) and 6848 of 1904. (See next abstract).—T. F. B.

Printing with Indanthrene and Flavanthrene. O. Imray, London. From Farbwerke vorm. Meister, Lucius und Brüning, Höchst on the Maine, Germany. Eng. Pat. 6848, March 21, 1904.

THE method described in Eng. Pat. 13,116 of 1903 (this J., 1904, 544) for printing with indigo by the aid of stable aldehyde-hydrosulphite compounds described in Eng. Pat. 5867 of 1903 (this J., 1904, 369) is also applicable to printing with Indanthrene or Flavanthrene; instead of using the aldehyde-hydrosulphite compounds, ketone-hydrosulphite compounds of Eng. Pat. 6216 of 1904 (see above) may be used. As an example of method, a solution of formaldehyde-sodium-hydrosulphite (120 grms.) in water (80 c.c.) is stirred into an alkali thickener (650 grms.) consisting of British gum (1 part) and caustic soda lye 40° B. (9 parts), and a 20 per cent. Indanthrene paste (120 grms.) is added. The fabric is printed with this mixture, steamed, washed, soaped if necessary, and dried.—T. F. B.

Centrifugal Machine [for Textiles, &c.]. A. J. B. London. From The A. T. Hagen Co., Rochester, U.S.A. Eng. Pat. 26,487, Dec. 5, 1904.

A CENTRIFUGAL machine is fitted with an arrangement of springs to balance the journal box and with an automatic lubricating apparatus.—A. B. S.

Woollen Fabrics, Flannel, Wadding, Muslin, Canvas, and the like; Process or Dressing for Rendering — Unflammable. M. Lindsay, Dalton in Furness, Lancs. Eng. Pat. 6568, March 18, 1904.

THE material to be fireproofed is impregnated with a solution of "saltpetre" (2 parts); borax (2 parts); alum (4 parts); and ammonium chloride (1 part); in water (120 parts).—T. F. B.

UNITED STATES PATENTS.

Dyeing Silk [after Weighting]; Process of —. J. Weidmann, Paterson, N.J. U.S. Pat. 780,924, Jan. 24, 1905.

VII.—ACIDS, ALKALIS, AND SALTS.

Potassium Hydroxide Solutions and solid Caustic Potash; Potents of Carbonate in Electrolytic — F. Winteler, *electrochem. and Metall. Ind.*, 1905, 3, 16—17.

ANALYSES of 19 samples of European electrolytic caustic sh are given, which show a variation in the potassium oxide from 73.3 to 81.8 per cent., and in carbonate from 2.4 to 18.4 per cent. As the solution produced in electrolytic process is free from carbonate, the carbonate these samples must have been formed during the operation and casting. Care should be exercised in the operations to protect the product as completely as possible from carbon dioxide. It was found by experiment that potassium hydroxide solutions of about 1 p. gr., shaken while hot with solid potassium carbonate, then allowed to cool to 20—22° C., contained from 33 to 55 grms. of carbonate per litre (with 700 to 760 grms. hydroxide); this then is the maximum amount which a concentrated solution can form by absorption of carbon dioxide, and any greater amount present in solid must have been formed during the casting process. When the hydroxide containing carbonate is left to solid in the melted state for some time, most of the carbonate settles to the bottom, and the upper clear part, when poured off into drums, gives a product containing more than 3–5 per cent. of carbonate. The red sediment on the bottom of the pots is dissolved and utilised by lime, then evaporated down and fused.

—J. T. D.

Magnesia; Formation of — from *Magnesium Carbonate* heat, and *Effect of Temperature on the Properties of the Product*. W. C. Anderson. *Chem. Soc. Proc.*, 1905, 21, 11.

THE author heated specimens of native magnesite, and of the forms of artificial magnesium carbonate, viz., "light," "crystal" and "heavy"; and determined: (1) the temperature at which carbon dioxide was first evolved; (2) the rate of evolution of the carbon dioxide; (3) the solubility in water of the magnesia produced. Native magnesite yielded 0.4 per cent. of its weight of carbon dioxide in 20 hours at 350° C., and the rate of evolution increased rapidly with rise of temperature. In the case of the artificial carbonates, the carbon dioxide was completely expelled at about 750° C. from the "light" and "crystal" forms, but only above 810° C. from the "heavy" carbonate. The magnesia prepared by heating "heavy" carbonate at a temperature not much above that needed for complete decomposition, dissolved in water more readily than the specimens prepared from the "light" and "crystal" forms under similar conditions. When the temperatures of preparation were increased, the rate of solution diminished in every instance, but much more rapidly in the case of the "heavy" oxide, than in the case of the other two. The author concludes that magnesia becomes polymerised on heating, and that the rate proceeds faster in the dense "heavy" oxide than in the lighter specimens. The rate of solution is probably a measure of the rate of hydration, and this appears to be most rapid in the magnesia prepared by heating the "heavy" carbonate at 810° C.—A. S.

Ammonium Salts; Hydrolysis of — V. H. Veley. *Chem. Soc. Trans.*, 1905, 87, 26—33.

SOLUTIONS of ammonium salts were boiled under a reflux condenser and the loss of ammonia determined. The results indicate that the evolution of ammonia is due to direct dissociation, but to hydrolysis of the salts. Three cases are presented: (1) the hydrolysis is *nil* or inappreciable—with the bromide, chloride and benzenesulphonate; (2) the hydrolysis is dependent upon dilution—with the nitrate and sulphate; and (3) the hydrolysis is independent of the dilution when beyond a certain limiting value—with the chlorate, mono- and di-phosphate, and acetate and other salts of weak organic acids. The persistence with which the several acids retain ammonia in combination corresponds to their activity in causing hydrolysis of methyl acetate, and inversion of cane sugar, the relative order of magnitude

being the same in all three chemical changes. In the following table, which gives the results obtained with $N/10$ solutions, K is 10 times the percentage molecular loss of ammonia or $P \times 10^3$, where P = loss of ammonia, and M = amount of ammonia originally combined:—

Salt.	Value of K	Salt.	Value of K.
Bromide	<i>nil</i>	Acetate	94.0
Chloride	1.4	Oxalate	22.3
Benzenesulphonate	4.0	Succinate	243.8
*Nitrate	38.9	Citrate	275.0
Sulphate	14.3	Ethyl-sulphate ..	11.1
Chlorate	20.3	Benzoate	10.6
Monophosphate ..	22.3	Salicylate	16.0
Diphosphate	40.0	Naphthalene sulphonate ..	15.0
*Formate	20.1		

* In the case of the nitrate and formate, the results are probably complicated by secondary reactions.

—A. S.

Oxygen; Withdrawal of — by *Platinum*. A. Magnus. *Physik. Zeits.*, 1905, 6, 12—13. *Chem. Centr.*, 1905, 1, 337.

THE author considers that the method described by Goldstein (see this J., 1904, 1147) for the removal of oxygen from gases is not quite trustworthy, and he recommends proceeding as follows:—Platinum or iridium is heated electrically nearly to whiteness; the current is led through wires that dip into mercury. The decrease of pressure in the case of air amounted to 20.7 per cent. in 20 minutes. Greater pressures can be used than in Goldstein's method, as the mercury can, if necessary, be placed in long barometer tubes. The absorption ceases after the withdrawal of the oxygen, whereas in discharge tubes, other gases also are absorbed, although more slowly. Iridium is more active than platinum. Palladium disintegrates too rapidly, the disintegration being due to a chemical process, not to sublimation.

—A. S.

Chlorine, Electrolytic; Utilisation of — O. Nagel. *Electrochem. and Metall. Ind.*, 1905, 3, 16.

IT is more profitable to convert electrolytic chlorine into hydrochloric acid than to make it into bleaching powder. The plan suggested is to blow the chlorine, mixed with steam, through glowing coke. The reaction is expressed by the equation: $Cl_2 + 3H_2O + 2C = CCl_2 + CO + 2HCl + 2H_2$; the excess of hydrogen secures that there shall be no free chlorine in the acid. The mixture of gases is led through absorbing towers, and the gas escaping from these can be used for fuel or for power. In practice, two coke-columns would be used alternately, one being blown up by air to the requisite temperature (about 1000° C.), while the reaction is going on in the other. After one minute's blowing, hydrochloric acid can be made for seven or eight minutes.—J. T. D.

Phosphorus; Manufacture of — W. Hempel. *Z. angew. Chem.*, 1905, 18, 132—136.

THE author has investigated the Pelletier process for the manufacture of phosphorus (conversion of tricalcium phosphate into monocalcium phosphate by means of sulphuric acid, and reduction of the product by charcoal). To render the whole of the phosphate soluble, a considerable excess of sulphuric acid over that needed for the conversion of the tricalcium- into the monocalcium salt must be used. If the excess acid be neutralised by barium hydroxide, more free acid is formed on concentration, the monocalcium salt forming the dialcium salt and free phosphoric acid. As the liquors containing sulphuric acid are concentrated, the amount of sulphuric acid retained diminishes, though not in inverse proportion to the concentration; and when by concentration a specific gravity of 1.28 is reached, corresponding with a sulphuric acid content of 4.2 per cent., phosphates begin to crystallise, so that further concentration is impracticable. Great difficulties were found in devising an apparatus in which to study the reduction of phosphorus, as fireclay vessels

were found to be very porous to the vapour (probably an important cause of the loss in the process as actually worked), while porcelain retorts were liable to choke and explode. The complete collection, too, of the phosphorus could not be ensured by any number of wash-bottles through liquid, but was eventually accomplished by entering the gases upward through a bed of a uniform fine-grained solid (small garnets).

The experimental apparatus is shown in the figure.—

The furnace is a porcelain tube A, surrounded by a spiral wrapping of a nickel wire (8.5 m. long, 1 mm. diameter), and jacketed by an outer fireclay tube, the whole packed in kieselguhr in a wooden box. At one end a thermo-electric pyrometer passes air-tight through a plug *a*; at the other the wide tube *l* (provided with the small side-tube *m* for taking samples of the gas) dips under the water in the wash-bottle B, through the lid of which passes the tube *c d* leading into the gas-filter, built up of the glass portions *b* and *i* and the sheet metal portion *k*, the last carrying a sieve *l* on which is laid a layer of garnets of 2-3 mm. mean diameter. From the filter the gases pass through the final wash-bottle D, and the meter E into the atmosphere. The mixture for reduction having been placed in the tube and all made tight, the temperature was gradually raised by passing a current through the nickel wire. From 300° to 600° C. all the sulphuric acid present was evolved as sulphur dioxide. At 700° C. the evolved gas became combustible. At 740° C. traces of phosphorus could be detected, but it did not come away in quantity till 960°; and at 1170° C. the distillation was practically over. Early in the process, the gas evolved was a mixture of carbon dioxide, carbon monoxide, and hydrogen; but the amounts of the first and last gradually lessen, and during the distillation of the phosphorus the accompanying gas consists almost entirely of carbon monoxide. There was accounted for in the condensing apparatus about 92.5 per cent. of the phosphorus contained in the experimental mixture; but a considerable proportion of it refused to melt together, and had to be determined (after separating and directly weighing the portion that would do so) by oxidation and weighing as magnesium pyrophosphate. The cause of this behaviour is probably a slight admixture with solid or liquid hydrogen phosphide, though no gaseous hydrogen phosphide was detected amongst the gases. An experiment with metaphosphoric acid showed that a good yield of phosphorus is not obtainable by reducing this substance with charcoal.

Wöhler long ago proposed to reduce a mixture of tricalcium phosphate and silica with charcoal, according to the equation $\text{Ca}_3\text{P}_2\text{O}_8 + 3\text{SiO}_2 + 5\text{C} = 3\text{CaSiO}_3 + 5\text{CO} + 2\text{P}$; but the process never succeeded owing to the difficulty of attaining the requisite temperature or of finding vessels to withstand it. Electric heating, however, has lessened or removed these difficulties, and an experiment was made on this process in the apparatus. Gas began to be evolved at 700° C., and became inflammable

at 1000° C.; phosphorus was detected at 1150°, began to distil in quantity at 1200°, and the distillation ended at 1450° C. The yield was 92 per cent. (another experiment at higher temperatures gave no higher yield) very little was in the "killed" condition. Electric heating has lately been adopted in German works, the retorts are sheet-iron cylinders lined with fireclay, the lower part of which carbon electrodes are introduced. The materials are fed in continuously, and the residue

slag continuously removed. Perfect dryness of the materials is an important factor in increasing the yield.—J. T.

Diamonds; New Technical Method for Cleaning—M. C. Schuyten. *Handelingen van het achtste Vlaamsche Natuur- en Geneeskundig Congres, gehouden te Antwerpen op Sept. 25, 1904.* Chem. Centr., 1905, 1, 411.

In order to avoid injuring the health of the workmen, the author recommends that the diamonds after being ground, be cleaned by treatment with fused potassium bisulphate, instead of, as is usual, by boiling with sulphuric and nitric acids.—A. S.

Alkali Heptamolybdates; New Iodometric Method for the Determination of —. B. Glassmann. XX, page 211.

ENGLISH PATENTS.

Sulphuric Acid; Concentration of — and Apparatus therefor. J. Mackenzie, Middlesbrough, Yorks. Eng. Pat. 26,278, Dec. 2, 1904.

THE dilute acid from a tank supported on the top of a tower, passes into a lead coil or coils, set in the path of the hot gases issuing from the tower. The latter is filled with acid-resisting bricks, down which the acid issues from the lead coil flows, and meets an upward current of waste fire-gases from a furnace. The acid then passes into a cast-iron concentrating pot, the lid of the upper part of which are lined with stoneware, and which is heated, in part or wholly, by waste gases from a pyrolytic kiln or furnace. A current of hot air is passed through the acid in the concentrating pot.—E. S.

Neutral Sulphate and Sulphurous Acid; Manufacture of — from Bisulphate. C. Bollé, Manchester. Eng. Pat. 6898, March 22, 1904.

THE bisulphate is heated in a cast-iron retort, provided with a mechanical agitator, with about 12 per cent. of wood shavings and 2 per cent. of coke dust, until the sulphurous acid formed (which is collected) is expelled, and only normal sulphate remains.—E. S.

Carbonate of Ammonia; Impts. in, and Apparatus for, the Manufacture of —. F. Lennard, Hove, Sussex. Eng. Pat. 5603, March 7, 1904.

In order to manufacture ammonium carbonate free from oil, the sublimers, condensers, and other vessels are formed of aluminium, or have those parts which come into contact with the ammonium carbonate formed of aluminium.—E. S.

Substances [Peroxides] containing easily liberated Oxygen; Preparation of —. G. F. Jaubert, Paris. Eng. Pat. 1,387, Oct. 5, 1904. Under Internat. Conv., Oct. 11, 1903.

See Fr. Pat. 336,062 of 1903; this J., 1904, 323.—T.F.B.

Sodium Perborate; Manufacture of —. G. W. Johnson, London. From the Deutsche Gold und Silber-Scheideanstalt vorm. Rosler, Frankfurt-on-Maine, Germany. Eng. Pat. 22,004, Oct. 12, 1901.

MOLLECULAR proportions of boric acid and sodium or lithium-potassium peroxide, are mixed in cold water, and an equivalent proportion of an acid that forms an easily soluble salt (such as hydrochloric acid) is added, the temperature being kept at or below 5° C. The sodium perborate settles as a crystalline powder, which is washed with ice water, and dried.—E. S.

Ferric Sulphate; [Electrical] Manufacture of Basic —. W. Garraway, Glasgow. Eng. Pat. 26,314, Dec. 2, 1903.

A FERROUS sulphate solution is placed in cathode compartments provided with iron cathode plates, whence it passes to anode compartments (separated from the former by wood porous earthenware partitions), at the bottom of which a number of lead anode pipes, in which latter compartments basic ferric sulphate is formed by the action of the electric current derived from a suitable source. The product is applicable to the precipitation of sewage, and to other purposes.—E. S.

UNITED STATES PATENTS.

Tin Oxide; Process of Making —. H. Foersterling, Perth Amboy, N.J., Assignor to The Roessler & Hasselacher Chemical Co., New York. U.S. Pat. 780,984, Jan. 31, 1905.

A MOLTEN bath of tin is maintained in a suitable furnace with its surface swept by a current of previously heated air, at a temperature above that at which the "lower coloring tin oxides" are formed, and tin is gradually oxidized as the bath is depleted. The tin oxide is removed as it forms.—E. S.

Aluminium and Sodium; Making the Double Sulphate of —. G. E. Hipp, Buffalo, N.Y. U.S. Pat. 781,341, Jan. 31, 1905.

A SOLUTION of nitre cake is treated with a small proportion of an alkali sulphide, and an "aluminous product" is added to the filtered solution, which is then again cleared, and aluminium sulphate solution is added in proportion suitable to form the double sulphate. About 0.5 per cent. of free acid is then added, and the whole is concentrated and calcined.—E. S.

Cyanides; Process of Making —. J. Tcherniac, Freiburg, Germany. U.S. Pat. 781,472, Jan. 31, 1905.

See Eng. Pat. 17,449 of 1903; this J., 1904, 714.—T.F.B.

Graphite; Separating — from Wollastonite. S. R. Krom, Plainfield, and S. V. Krom, Jersey City, N.J. U.S. Pat. 780,297, Jan. 17, 1905.

THE wollastonite (calcium silicate) ore carrying graphite is crushed, and the greater part of the graphite is concentrated in the dry way. The concentrate passes by gravity into a bath of dilute sulphuric acid, which decomposes

the wollastonite with formation of calcium sulphate, from which the product is washed free. The residual mixture of graphite with insoluble silica is dried, and is then subjected to mechanical treatment for the separation of pure graphite.—E. S.

VIII.—GLASS, POTTERY, AND ENAMELS.

China; Bone as a Flux in English —. H. W. Edwards. Trans. Engl. Ceramic Soc., 1903-4, 32-36.

THE author made a series of experiments on the action of calcium phosphate in china bodies. It was found that mixtures containing pure precipitated tricalcium phosphate yielded ware quite as translucent and showing no greater fusibility or tendency to warp than that obtained with the ordinary bone mixture; also that addition of calcium fluoride to the phosphate had no effect on these properties. When mixtures containing commercial precipitated phosphate was used however, the ware completely lost its shape in firing, probably owing to the phosphate containing alkali, in consequence of deficient washing. The author considers that in the ordinary china body, about one-third (15 per cent.) of the total calcium phosphate (45 per cent.) acts as a flux, whilst the remainder by reason of its translucency and whiteness, improves the quality of the ware. The action of the phosphate as a flux is considered to be due to the formation of a calcium disilicate, $\text{CaO} \cdot 2\text{SiO}_2$, or of a fusible double silico-phosphate. The loss on firing is reduced, because the uncombined phosphate in excess remains infusible, and holds up the body even beyond the temperature at which the fusible constituents melt.—A. S.

Underglaze Pink; Colouring Agent in —. W. A. Lethbridge. Trans. Engl. Ceramic Soc., 1903-1904, 9-15.

THE author prepared a series of "pinks" by moistening equal portions of, in one case, calcium stannate and in the other mixtures of tin dioxide and whitening with varying proportions of a solution of ammonium bichromate. The mixtures were dried, fired, cooled, and washed with hot water. It was found that all the products contained a fairly constant amount of chromium, notwithstanding the varying quantities of ammonium bichromate added. The author concludes from his results that Petrik's view that the colouring agent is chromium oxide resting on a base of tin dioxide is correct. (See this J., 1892, 748; also 1903, 28.)—A. S.

ENGLISH PATENT.

Pottery Ware; Manufacture of —. J. H. Fleming, Tunstall. Eng. Pat. 8602, April 14, 1904.

IN the stacks which support the ware in the glost oven are formed a series of preferably rectangular or approximately parallel sided pockets. Into each of these a supporting arm or pin slips in such a way (see figure) that the pins can readily assume either of two positions, viz., one a substantially horizontal position when in use supporting the ware, and the other an inclined position with the long axis of the pin practically in line with the pocket so that the articles can easily be lifted out. The pins may have their back portions bevelled to allow for the turning movement, and two bevelled shoulders are formed on each pin to assist in taking the weight of the article, and are themselves protected by the front edge of the pocket. Three stacks are preferably employed together to form a triangular "crank" in which the ware is placed.—A. G. L.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Portland Cement, Detector of False L. A. Balkoff. XXIII, page 249.

ENGLISH PATENTS.

Kilns, Construction of, for Making L. A. Reid, Loughton, Staffs. Eng. Pat. 1339, Jan. 19, 1904.

Upon a suitable foundation is fixed a metallic foot-step for supporting an upright shaft securely bolted, centrally, at its upper end to the underside of a horizontal iron plate, which carries a toothed metallic ring or rack underneath. Nearer to the centre of the plate, are bolted the upper ends of a number of brackets at suitable distances apart, each supporting a wheel vertically at the lower end. The wheels run on a metal plate or on rails secured to the foundation. On the upper surface of the revolving plate is erected an iron casing, within which is placed a number of fire-brick firing chambers furnished with flues. A fire-box and flue are also provided, mounted on a metal truck with wheels travelling on rails. The goods in a firing chamber are heated by bringing this fire-box close up to the chamber and opening the sliding door.—A. G. L.

Macadamised Roads and the Like, and Solutions to be Employed therein. J. C. Butterfield, London. Eng. Pat. 1776, Jan. 23, 1904.

THE road is watered during construction with water containing 20 to 40 per cent. of a mixture prepared as follows: crude Texas oil, or other oil of a similar nature, is heated to 180 to 190° F. in a tank, either steam-jacketed or with an internal copper coil. About 6 in. above the bottom of the vessel is placed an iron or copper coil provided with $\frac{1}{8}$ -in. or $\frac{1}{4}$ -in. trumpet-shaped holes on its under side, causing air blown through the coil to strike against the bottom, and then bubble upward, oxidising and agitating the oil at the same time. Heating and blowing of the oil are carried on for two or three hours to drive off some of the volatile compounds and improve its odour. A solution of asphalt or pitch, made by heating it together with oil or benzine in an autoclave, under a pressure of 40 to 50 lb. per sq. in., is then added in such quantity that the finished product shall contain 10 to 20 per cent. of asphalt, the whole being mixed by blowing for 20 or 30 minutes, after which from 15 to 25 per cent. of water is run in together with 6 per cent. of rosin oil, 4 of oleine, 4 of "soda," and 10 of sodium silicate solution of 120 Tw. (all calculated on the finished product). After further blowing for 30 minutes, 1 per cent. of ammonia (sp. gr. 0.880) is added and the blowing continued very gently for another 10 to 15 minutes. The contents of the tank are then run into coolers and when cold are ready for use.

Instead of adding the sodium silicate solution to the mixture, it may be applied directly to the road, in the form of a solution at 28 Tw. This is allowed to nearly dry and then the asphalt mixture, made as above, but without any sodium silicate, is sprinkled on the road.—A. G. L.

Lim and Sand Bricks or Blocks; Manufacture of. — E. Stöffer, Zürich, Switzerland. Eng. Pat. 11,523, May 19, 1904.

A MIXTURE of sand and caustic lime (dry) is ground in open or closed vessels with the addition of water or steam, and the ground product made into bricks; these are then placed in drying frames, and may be steam-hardened if sufficient silicate of lime has not been formed in the preliminary process. —A. G. L.

Bricks and other Clay Products; Hot Air Drriers for Drying. — F. Richards, Rochester, Pa., U.S.A. Eng. Pat. 26,270, Dec. 2, 1904. Under Internat. Conv., June 20, 1904.

A NUMBER of parallel tunnels is provided, each having an underlying flue extending substantially for its whole

length, and a paved floor radiating heat, composed of bricks and T-bars separating the tunnel from the flue. An arched furnace-chamber and furnace are placed under the delivery end of the tunnel, into which heated air led through ducts along the top and sides of the furnace-chamber. The flue is divided to form a central flue, a parallel return side flues, a flue provided with a damper being placed near the inlet end of the tunnel into which the side flues empty. The tunnels have floor-openings communicating with a duct connected with the stack whereby heavy moisture-laden air may be withdrawn, and they are also provided with openings in their roofs leading to a breeching connected with the stack.—A. G. L.

Binding Material or Plastic Composition; Manufacture of a —, for use in the Production of Moulded Articles or for Other [Electrical] Purposes. L. Grote and Perry, both of London. Eng. Pat. 21,842, Oct. 1903.

A SOLUTION of chloride of lime (chlorinated lime) is treated with magnesium sulphate, and the solution of magnesium hypochlorite obtained is concentrated to about 20° B., and mixed with a vegetable gum, such as tragacanth, 10 parts of gum being used to 200 of the above liquid. The composition is allowed to stand for 12 to 14 hours, afterwards sieved and mixed with an alkali silicate, preferably a double silicate of sodium and potassium 10 to 25 parts of the latter at 10° to 20° B. being mixed with 210 parts by weight of the composition, though for some purposes a stronger or weaker solution of double silicate may be advantageously employed. A non-hygroscopic material, which is obtained, is used as a binding organic or inorganic pulverisable material in order to produce moulded articles, or the composition may be used as a fire-proof, water-proof, and if necessary acid-proof insulating material for electrical purposes. —B. N.

Magnesia Cement Composition, and Process of Making same, applicable to Making Artificial Stone and Like. E. Bittel and G. K. Nutz, West Hoboken, and G. J. Bittel, Jersey City, U.S.A. Eng. Pat., 57, March 8, 1904.

SEE U.S. Pat. 757,252 of 1904; this J., 1904, 491.—T. F.

Cement for use in Electric Lamps and for other Purposes; Manufacture of. — Cleminson Electric Lamp Attachment, Ltd., and W. King, Manchester. Eng. Pat. 6600, March 18, 1904.

A NITRATED cotton or cellulose, such as dinitrocellulose or collodion-cotton, is dissolved in a suitable solvent, which is added a solution in spirit of sandarac, shell or other gum. Mica, slate, or other inert, non-conducting powder and sulphur or calcium sulphate are then mixed with the liquid, to which aniline or other colours may also be added. Suitable proportions are 20 per cent. mica, 34 of sandarac, 45 of sulphur, and 1 of nitrated cotton.—A. G. L.

UNITED STATES PATENTS.

[Brick] *Drier.* J. M. Rumbaugh, Wilkinsburg, Pa. U.S. Pat. 780,914, Jan. 24, 1905.

A FURNACE with a flue leading to a stack has a drying chamber situated above. By an arrangement of dampers operated from without the furnace, the heat from the latter may be directed through the flue to the stack, heating the drying chamber by radiation, or the hot gas may be taken directly through the drying chamber, where they are cut off from the flue. A separate stack is then provided to maintain sufficient draught to keep the furnace alight. From the roof of the drying chamber are hung heat retarders or deflectors, and on the bottom thereof a track for trucks carrying the bricks to be dried. The claim extends to the combination of two or more furnace flues and drying chambers into a battery.—W. H. C.

Roadways; Method of Forming or Treating. — [for the Prevention of Dust]. F. W. A. Loebell, Muenchen, Germany. U.S. Pat. 781,079, Jan. 31, 1905.

SEE Fr. Pat. 345,067 of 1904; this J., 1904, 1218.—T. F.

X.—METALLURGY.

and its Alloys; Effect of Liquid Air Temperatures on the Mechanical and other Properties of —. J. A. Haddfield. Roy. Soc. Proc., 1905, 326–336.

The effect of liquid air temperatures on iron and iron alloys, with certain exceptions, is to increase greatly their tensile stress, and to decrease their ductility to practically nothing. This holds good for the softest light irons, as well as for steel with from 0.10 to 1.50 per cent. of carbon. Specimens of Swedish charcoal iron immersed in liquid air, and immediately struck with a hammer, broke instantly. The hardness number of the iron, as found by the Brinell hardness ball test, varied from 90 at ordinary temperature to 266 at -32° C. Nickel, on the other hand, shows not only increased tenacity, but also increased ductility, at low temperatures, although at ordinary temperatures the ductility of iron is greater than that of nickel. Hence the addition of nickel prevents iron from becoming brittle at low temperatures. Thus, with an alloy containing 1 per cent. of carbon, 24.30 of nickel, and 6.05 of manganese, the elongation increased from 60 at ordinary to 7.5 per cent. at the low temperature, whilst the yield stress rises from 51 to 84 tons. This result is all the more remarkable since the presence of manganese alone renders iron still more brittle at low temperatures than in the case with iron free from manganese.—A. G. L.

Extractions from Gold Ores and Tailings; Use of Ammonia and its Compounds in Cyaniding —. A. Jarman and Le Gay Brereton. Inst. of Mining and Metall., 16, 1905.

The authors made a series of experiments mainly along the lines of Hunt's process (see this J., 1903, 95). They found that for quartzose gold ores containing cyanides, especially copper carbonate, ammonium cyanide is a more efficient solvent for the gold than potassium cyanide alone, but not so good as the latter in presence of a small amount of ammonia. The amount of ammonia required to protect potassium cyanide solutions from dissolving large quantities of copper increases with the strength of the cyanide solution, but is not affected by the amount of copper up to 3 per cent. With more than 3 per cent. of copper, a larger amount of ammonia is necessary to obtain a good extraction of the gold. With ores containing from 1.5 to 3 per cent. of copper, and with a 0.25 per cent. solution of potassium cyanide, the best extraction is effected in presence of 0.1 per cent. of ammonia. A mixture of ammonia and potassium cyanide can be prepared which dissolves less copper carbonate than either of the components alone; and the composition of this mixture is very near that of the solution which gives the best gold extraction (i.e., when using small percentages of ammonia). During the treatment, the amount of dissolved copper first rapidly rises to a maximum, but afterwards diminishes steadily, while at the same time the quantity of gold dissolved, increases.—A. S.

"White Precipitate"; Formation of the — in the Precipitating Boxes of Cyanide Works. B. Bay. J. Chem., Metall. and Mining Soc., S. Africa, 1904, 5, 8–149. (See this J., 1904, 1031, 1149.)

The author finds that if a solution of zinc cyanide in potassium cyanide be allowed to stand in contact with zinc shavings, a white precipitate is produced if the shavings be only partly covered and thus remain exposed to the air, whilst the solution remains clear if the zinc shavings be completely covered by it. The precipitate produced, contains zinc and cyanogen, and probably consists of a mixture of zinc cyanide and hydroxide.—A. S.

Material [Slimes, &c.]; Preparation of — for Smelting. T. J. Greenway. Eng. and Mining J., 1905, 1, 73.

In the preparation, for smelting, of the silver-lead con-

centrate and slime resulting from the concentration of Broken Hill complex sulphide ore, the author obtained good results by a briquetting process, similar to that followed in making ordinary bricks by the semi-dry brick-pressing process. It is stated that the material is converted into hard, semi-fused lumps, and that most of the sulphur, arsenic, &c., is expelled; the cost, with labour at 25 cents per hour, and wood or coal at 4 dols. per ton, amounts to from 1 to $1\frac{1}{2}$ dols. per ton of material. A. S.

Zinc Retort; Metallurgy of Sulphur Compounds in the —. W. M. Johnson. Electrochem. and Metall. Ind., 1905, 3, 14–16.

A PROPERLY roasted ore should not contain as much as 0.1 per cent. of sulphur as zinc sulphate. The dissociation-temperature of zinc sulphate being 739° C., and the temperature in the roasting furnaces 200° – 300° higher, any notable quantity of zinc sulphate in the roasted ore implies faulty roasting. Ferrous sulphate decomposes at a still lower temperature than zinc sulphate. Lead sulphate exists in the roasted ore; but, though he has not made conclusive experiments on the point, the author is strongly of opinion that by no means all the sulphur combined with lead is present as sulphate. Lime, and under the ordinary conditions of roasting, magnesia, too, fix sulphur as sulphates. A roasted ore, too, will usually contain from 0.05 to 0.5 per cent. of sulphur as sulphides. It is uncertain with what metals this sulphur is combined, but for practical purposes it may be assumed to be present as zinc sulphide. This sulphide yields metallic zinc under the action of iron (action begins at 1167° C., and is very rapid at the melting point of cast-iron), or of carbon (1300° C.), though the latter reacts much less rapidly than the former. The reaction with iron produces ferrous sulphide, which is left in the retort; but the carbon bisulphide formed in the other reaction goes forward and tends to render the condensation of the zinc more difficult. Moreover, the reaction is to some extent reversed at the temperature of the condenser, and the fine carbon formed prevents the coalescence of the droplets of liquid zinc. The only disadvantage of the ferrous sulphide is that it acts somewhat rapidly on the fireclay of the retorts. The reactions of sulphates in the distillation are very complex, but in general it may be stated that all the oxygen and some of the sulphur they contain are converted into gaseous compounds, which act prejudicially on the condensation of the zinc, and also possibly cause some loss by reaction on the zinc at the lower temperature of the condenser with formation of oxide and sulphide.—J. T. D.

Cadmium; Method of Preparing Metallic —. C. Goldschmidt. Chem.-Zeit., 1905, 29, 79.

ALUMINIUM possesses the property of quantitatively precipitating the cadmium from solutions of soluble cadmium salts in presence of a trace of chromium nitrate.—T. F. B.

Nickel Steel; Manufacture of —. A. de Dion and G. Bouton, Puteaux, France. Eng. Pat. 24,175. Nov. 8, 1904. Under Internat. Conv., June 17, 1904. SEE Fr. Pat. 344,095 of 1904; this J., 1904, 1095.—T.F.B.

Silicated Ores (Simple or Complex) of Nickel; Treating —. M. Malzac, Paris. Eng. Pat. 1556, Jan. 21, 1904.

NICKEL ores, and especially such as those of New Caledonia or of Silesia, are digested with sulphuric acid (or other strong acid) and the mass is lixiviated, in some cases

with addition of ammonia to the washing water. The filtered solution is heated with lime, the ammonia expelled is recovered, and the product, freed from the precipitated calcium sulphate, &c., by filtration, is precipitated, preferably with addition of ammonia to facilitate the cohesion of the metals deposited. —E. S.

Gold or other Metal-Bearing Slimes; Process of Treating Same. — R. Knicker, London, Eng. Pat. 7658, March 31, 1904.

THE precipitating boxes charged with zinc or other metal shavings are formed of a number of separate units, or in pairs, mounted on wheeled trucks. These units are provided with suitable lips, so that the metal-bearing solution may flow from one unit to the next through the series. The units are interchangeable in position. To prevent tampering with the slime on the bottoms of the boxes, the frames and screens are locked in position, but the tops of the boxes are open. —E. S.

Metalliferous Materials; Vibrating Trough for Concentrating Fully Dissolved. — E. J. Swyny and S. G. Plucknett, Sydney, Australia. Eng. Pat. 19,141, Sept. 5, 1904.

THE vibrating trough or tank is divided into a series of connected channels in which the material, mixed with water, flows in a direction transverse to that of the vibratory motion and is agitated in a direction transverse to that of the flow. The first run or channel is supplied from a hopper chamber having inclined faces. Each channel is provided with a baffle plate at the end where it communicates with the adjacent one, and the mixture of water and mineral flowing over the baffles is met by a water-spray from a perforated pipe. —E. S.

Slimes, Tailings, and like Metalliferous Materials; Extraction of Normally Buoyant Mineral Particles from. — E. J. Swyny and S. G. Plucknett, Sydney, N.S.W. Eng. Pat. 19,142, Sept. 5, 1904.

THE process is intended specially for the extraction of the valuable sulphides and mineral particles from the waste slimes and tailings which have accumulated at Broken Hill, N.S.W. The material is thoroughly "pugged" and then transferred to a shaking screen which separates the larger particles, stones, &c. The finer material is conveyed together with water to an ore-classifier, such as is described in Eng. Pat. 19,139 of 1904 (this J., 1904, 1150), where it is separated into two grades, each of which passes to a separate concentrator of the type described in Eng. Pat. 19,141 of 1904 (see preceding abstract). —A. S.

Sulphide Ores; Reduction of —, and Recovery of [Precious and other] Metals therefrom. — H. R. Angel, Ealing. Eng. Pat. 24,136, Nov. 8, 1904.

THIS is an improvement on Eng. Pat. 1034 of 1897 (this J., 1898, 159), and consists mainly in the use of sodium sulphate combined with carbonaceous matter for the reduction of a mixture of raw and roasted sulphide ores containing lead. When the charge is at a red-heat, zinc oxide is added, which reacts so as to form "caustic soda," and the latter attacks the lead present in the raw ore, and this in turn will take up the lead from the roasted ore, and both will be precipitated, carrying down the precious metals. With wholly calcined ores, the use of zinc oxide may be dispensed with. (See also Eng. Pats. 801 of 1895; 9409 of 1897; and 14,523 of 1898; this J., 1896, 119; 1898, 461; and 1899, 769.) —E. S.

Furnaces for Roasting and Smelting and Analogous Uses. — U. Wedge, Ardmore, Pa., U.S.A. Eng. Pat. 27,973, Dec. 12, 1904.

SEE U.S. Pat. 777,577 of 1904; this J., 1905, 93.—T.F.B.

UNITED STATES PATENTS.

Metal-Leaching Process. — T. B. Joseph, San Francisco, Cal. U.S. Pat. 780,293, Jan. 17, 1905.

GOLD, silver, copper, zinc and nickel, are extracted from

their ores by leaching them with a solution containing sodium cyanide and ammonium bicarbonate, and may also contain "bromocyanide," and calcium hydroxide with or without barium dioxide, the ores being simultaneously agitated by injection of compressed air. (Compare U.S. Pats. 718,633, 728,397, and 732,639 of 1903, and 758,367 of 1904; this J., 1903, 214, 747, and 1904, 547.) —E. S.

Iron-Pyrites Briquette and Mode of Making same. — Wedge, Ardmore, Pa., U.S. Pat. 780,464, Jan. 17, 1905.

POWDERED pyrites is moistened, mixed with pyrites "smalls" or "fines" and the mass moulded into briquettes which are subjected to the action of air and heat to effect the production of sulphates from the oxidation of powdered pyrites, which sulphates act as a binding material. —E. S.

Magnetic Ore; Method of Agglomerating. — E. G. Chevy Chase, Md., Assignor to T. J. Mayer, Washington, D.C. U.S. Pat. 780,716, Jan. 24, 1905.

THE ore is fed from hoppers down two oppositely inclined channels, so mounted on metal supports serving as electrodes to a source of electricity, that the two streams of ore falling from the lower ends of the channels do not meet, an arc being thus established between the streams whereby the particles are fused into small lumps varying in size from that of a wheat grain to that of a bean. The fused lumps fall into an inclined cylinder upon an accumulation of previously fused and partly cooled particles with which further agglomeration takes place before discharge. —E. S.

Roasting Furnace. — A. R. Mayer, Assignor to The Union Zinc and Chemical Co., both of Kansas City, Mo. U.S. Pat. 780,115, Jan. 17, 1905.

THE furnace has a number of superposed hearths, all of which hollow stirrer arms extend from a central vertical shaft or pipe. Water is supplied at the top and is directed by means of conduits along the inner face of shaft, in which it is discharged through a series of perforated gutters placed at intervals within it. There are plates to close the communication between the arms and shaft, and inlet and outlet pipes extend through packing boxes in such plates. The hollow arms are detachably fitted to hollow bosses on the shaft. There are air inlets at the bottom, and air outlets at the top of the shaft. A tank is placed outside, which receives the flow of water passing down the shaft and circulating in the stirrer arms. —E. S.

Furnace for Roasting Ores, &c. — W. W. Tola, Kans. U.S. Pat. 780,387, Jan. 17, 1905.

THE claim is for a kiln for roasting ores, &c., with which furnace is combined, and travelling mechanism arranged adjacent to the kiln, by which bars to which rakes are attached, are set in motion and operated. The rake bars are protected from excessive heat by shields which encircle them as they enter the furnace. —E. S.

Alloys [Aluminium-Zinc]; Manufacture of Metallic —. — T. Prescott, Huddersfield. U.S. Pat. 781,300, Jan. 17, 1905.

SEE Eng. Pat. 5683 of 1903; this J., 1904, 443.—T.F.B.

FRENCH PATENT.

Lead (or Lead and Copper) Ores; Methods of Desulphurising and Smelting. — Soc. Anon. d. Mines de Bormettes, and A. Lottii. Fr. Pat. 346,527, Sept. 19, 1904.

THE crushed ore is added in suitable proportion to slag, as the latter flows from the furnace, and is agitated therewith, whereby the heat of the slag is utilised and the sulphur of the ore is partly expelled and partly oxidised to sulphur dioxide and trioxide. In some cases it is preferred that pyritic ore should undergo a prior partial roasting. The product of the described process is a spore

containing lead, partly as metal, and partly as oxide and as sulphate, in a suitable condition for subsequent smelting.—E. S.

Gases; Impts. in, and Apparatus for, Producing Reactions in —, by means of Electricity. J. Y. Johnson. London. From the Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. Eng. Pat. 5688, March 8, 1904.

This invention comprises a process of producing reactions in gases, such as the combination of nitrogen and oxygen, by subjecting the gases to the action of an electric arc or arc in the magnetic field of an inductive resistance or inductive coil, or inductive resistances or choking coils, when being excited by, and regulating, an alternating current or currents of electricity feeding the arc or arcs. Several methods of constructing the apparatus are shown, which a single-phase, two-phase and three-phase dynamo employed, also a single-phase dynamo with an auxiliary current and an arrangement of two three-phase dynamos to supply one furnace.—B. N.

(B.)—ELECTRO-METALLURGY.

Platinum; Electrolytic Solution of —. R. Ruer. *Z. Elektrochem.*, 1905, 11, 10—12.

The author raises objections to the application by Brochet and Petit of their explanation of the solubility of platinum under the influence of alternating currents to the case of sulphuric acid containing an oxidising agent is the electrolyte. Brochet and Petit have studied the solubility of platinum in amide solutions (this J., 1904, 1222; 1905, 33) which, however, give anomalous results. The author describes further experiments in confirmation of his view, that the solubility is favoured by the oxidising agent so weakening

the cathodic impulse, that the alternating current becomes unsymmetrical, and the anodic action, which is really answerable for the solution, is able to manifest itself. By using a solution of sulphuric acid containing a reducing agent, and alternately connecting a platinum electrode with the positive terminal of a source of current and allowing it to remain disconnected, he proves that the anodic action is alone necessary for the solution of the metal.—R. S. H.

Zinc Coatings; Properties of —. C. F. Burgess. *Electroch. and Metall. Ind.*, 1905, 3, 17—22.

The copper sulphate test for galvanised iron was found to be of little value in comparing hot galvanised and electrolytically galvanised plates; a corroding agent much more nearly imitating the conditions of actual practice was found in 2N/3 sulphuric acid. In resistance to this agent, electrolytic zinc is far superior to the metal applied in the molten condition, an electrolytic coating of 12 grms. per sq. ft. being as good as the ordinary galvanised coating of 28 grms. per sq. ft. An electrolytic coating of the latter weight is extremely durable. The electrolytic process is somewhat slow, and cannot be hurried without injuring the character of the coating; the best results are got with a current density of 14.4 amperes per sq. ft. The coating, too, cannot be deposited more heavily than about 30 grms. per sq. ft., or the outer layers become rough and crystalline. The area and distribution of the anode surface were found to have some influence on the deposit. Even distribution of current over corrugated and other irregular surfaces, and avoidance of thickness and roughness at the edges, are difficult to attain. The best results are got in solutions as nearly neutral as possible; free acid both decreases the current efficiency, and lowers the quality of the zinc as a protection. Tests of the strength of adherence of the coating to the iron have shown that the two metals are chemically separate, and that neither in the electrolytic nor in the hot galvanising process does any alloying occur.—J. T. O.

Metals of the Alkali Group; Production of —, by Electrolysis. E. A. Ashcroft. London. Eng. Pat., 7056, Mar. 23, 1904.

This invention comprises the process of producing an alkali metal, and consists in electrolysis a fused salt other than the chloride, such as the nitrate, sulphide, sulphate or hyposulphite, in an electrolytic cell over a cathode of fused lead which forms a fusible alloy with the alkali metal. The fused alloy is removed to a second electrolytic cell, where it is used as the anode with an electrolyte, such as sodium hydroxide or the like, which yields only the alkali metal at the cathode, the electrolyte not being consumed. Instead of using two separate cells, a combined two compartment cell may be employed with an intermediate electrode of fused lead.—B. N.

Metallic Surfaces; [Electrolytic] Method and Apparatus for Cleaning —. B. J. B. Mills. London. From T. A. Edison, Llewellyn Park, Orange, N.J. Eng. Pat. 26,947, Dec. 10, 1904.

The specification relates to a method of preparing metallic surfaces for the deposition upon them of a permanent metallic coating. The article to be cleaned is constituted the cathode in an electrolytic bath, an unattainable anode, as of carbon being used. Hydrogen is generated on the articles and mechanically carries off foreign matters therefrom, leaving a clean surface. The apparatus, as applied in cleaning long endless strips of thin sheet iron, intended to be nickel-plated for use in the construction of Edison's storage batteries, is shown in the figure in which the iron strip 3 passes over the insulated rollers 2—2, and leaves the solution through the tube 4 of glass

or hard rubber. 5 is the anode, which is preferably of graphite, with a 10 per cent. solution of potassium cyanide as the electrolyte.—E. S.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

Calophyllum Inophyllum Seed Oil, G. Fendler, Apoth. Z. 1905, 20, 6; Chem.-Zeit., 1905, 29 [Rep.], 15.

THE fruit examined was round, yellowish-brown to dark grey in colour, and 2.5 to 4 cm. in diameter. The seeds were yellowish white and soft, and contained from 50 to 55 per cent. of a greenish-yellow oil of bitter pungent

taste, which was soluble in all proportions in the usual solvents for oils, but was insoluble in absolute alcohol. It gave the following values:—Sp. gr. at 15° C., 0.92; Reichert-Meißl value, 0.13; acid value, 28.45; saponification value, 196; and iodine value, 92.8. By treatment with a solution of sodium hydroxide the oil yielded greenish resin of semi-liquid consistency, and soluble in alcohol. The fatty acids consisted, in the main, of palmitic, oleic and stearic acids. It is stated that the oil could be used in the manufacture of soap.—C. M.

Fats; Investigation of Insolated and Rancid

Winckel, Z. Untersuch. Nahr. u. Genussm., 1900, 90—96.

EXPERIMENTS described in detail have led the author to the following conclusions:—The changes that take place in fats in sunlight differ from those that take place in the dark (without development of rancidity), both processes of decomposition being due to chemical changes. In the case of fats become rancid, however, micro-organisms play a part in the process. The appearance of substances that give Kreis's reaction (violet colour with phloroglucin and hydrochloric acid) does not coincide with the development of rancidity in the fat. For instance, butter exposed to sunlight for an hour gave a faint reaction to this test without having the slightest odour or taste of rancidity. On the other hand, butter that had been strongly rancid in the dark gave no reaction, but did so after exposure to sunlight. The chemical changes in the decomposition of butter are of a different nature to those that occur in other fats. Rancidity in fats is best detected by means of the senses, since the reactions recommended for the detection of decomposition are not reliable in the case of butter and are too sensitive with other fats. The acid is the principal constituent taking part in the decomposition, and its decomposition products are the cause of the above-mentioned reactions. (See this J., 359, 610; 1900, 356; 1903, 575; 1904, 988).—C. M.

Cottonseed Oil; Investigation of Halphen's Reaction

K. Fischer and H. Peyan, Z. Untersuch. Nahr. u. Genussm., 1905, 9, 81—90.

IT has been shown by previous observers (this J., 611, 711, 865; 1900, 73) that the coloration given by Halphen's reaction is considerably weakened by heating the oil to 200° C. and that the active substance is destroyed at 250° C., though the oil is then so altered as to be unfit for food. In the authors' experiments no weakening of the reaction was produced by treating the oil with reducing agents, such as zinc and sulphuric acid, but treatment of the oil with chlorine or with sulphuric acid rendered it completely inactive, though again treated with chlorine could not be made fit for food. The treatment with sulphurous acid followed by thorough washing with alcohol yielded inactive products that could not be distinguished from normal cottonseed oil. The authors' general conclusion is that it is possible to treat cottonseed oil so that it gives no reaction in either Halphen's or Beechi's test, and that the phytosterol test is the only reliable means of detecting the addition of small quantities of such oil to lard.—C. M.

Oils; Influence of Moisture on the Oxygen-absorption of

H. W. Lippert, Z. angew. Chem., 18, 94—95.

IN continuation of his former experiments (this J., 358, and 1903, 562) on the absorption of oxygen by oils, the author has experimented with oils to which no preservatives had been added, using for this purpose: (1) fresh linseed oil; (2) very old linseed oil; and (3) hempseed oil, 4 years old. Each of the oils was found to dry more rapidly in absolutely dry air than in moist air. However, even traces of manganese are present, the reverse is the case. The drying of a varnish, therefore, depends not only upon the method of manufacture and quality of materials used, but upon the condition of the atmosphere. Chemical analysis is therefore insufficient for judging of the quality of a sample, unless supplemented by drying tests such as those suggested by the author.—H. B.

XIII.—PIGMENTS, PAINTS ; RESINS, VARNISHES ; INDIA-RUBBER, Etc.

(A.)—PIGMENTS ; PAINTS.

ENGLISH PATENT.

Colours from Sulphur [Sulphide] Dyestuffs ; Manufacture of Colours — C. D. Abel, London. From Act. of f Anilinfabr., Berlin. Eng. Pat. 6217, March 11, 1904.

(B.)—RESINS ; VARNISHES.

Resins ; Study of some African — C. Collignier. Bull. Soc. Chim., 1905, 33, 169—176

The author has examined three specimens of African resins known commercially as Kissel (*Gomme caillou*), Kisserin (Cameroon), and Accra, adopting the same methods as in previous researches (this J., 1903, 808).

	Kissel.	Kamerun (Cameroon).	Accra.
Sp. gr. at 27° C.	1.066	1.052	1.033
Melting point	110°C	150°C.	120°C.
Acid value	70.4	159.7	97.8
Saponification value .	117.8	70.0	140.0

The solubility of the resins in various solvents was determined.

Though the resins are practically completely soluble in lime and amyl acetate, these solutions are not true varnishes. The Cameroon copal is the only one of the three from which satisfactory varnishes can be manufactured.—M. J. S.

(C.)—INDIA-RUBBER, &c.

Dinitro-Caoutchouc, Weber's — C. Harries. Ber., 1905, 38, 87—90.

The author has studied the action of nitrogen peroxide on caoutchouc, but has not been able to obtain a product of the composition of Weber's so-called dinitro-compound or nitrosate, $C_{10}H_{16}(NO_2)_2$ (see this J., 1903, 47, 1211). The composition of the product corresponds much better to that of the author's "nitrosite c" ($C_{10}H_{15}N_3O_7$)₂, obtained by the action of nitrous acid on caoutchouc (this J., 1901, 1123 ; 1902, 1404 ; 1903, 103, 875). The effects of the action of nitrogen peroxide and of nitrous acid on caoutchouc are quite similar, the product of the action becoming more soluble in ethyl acetate and in benzene, and also more stable as the action of the reagent is prolonged ; but with nitrogen peroxide it is much more difficult to obtain the final product of constant composition than with nitrous acid. These results show that Weber's "dinitro" method for the determination of caoutchouc (this J., 1903, 1211) may lead to incorrect results.—A. S.

Caoutchouc ; Nitrosites of —, and their Application in the Analysis of Raw Rubber and Rubber Goods. P. Alexander. Ber., 1905, 38, 181—184.

The author has obtained satisfactory results in the determination of caoutchouc in vulcanised rubber goods by Weber's method (this J., 1903, 1211), but on preparing the so-called dinitro compound from numerous specimens of raw rubber, it was found that not in a single case did the composition of the product agree even approximately with Weber's formula, $C_{10}H_{16}N_2O_4$. In general the products corresponded more closely to Harries' "nitrosite c" ($C_{10}H_{15}N_3O_7$)₂ (this J., 1902, 1404 ; 1903, 103, 875), which contained more carbon and less nitrogen than this. The author concludes that the product obtained from raw rubber by Weber's method consists chiefly of Harries' "nitrosite c," mixed with varying quantities of oxidation products formed by the action of the oxygen, which is reduced along with nitrogen peroxide by the decomposition of lead nitrate.—A. S.

ENGLISH PATENT.

Caoutchouc [from Guayule] ; Production of — M. Marx, Heidelberg, Germany. Eng. Pat. 28,051, Dec. 21, 1904. Under Internat. Conv., Sept. 21, 1904.

THE Mexican plant known as guayule is finely divided and heated with an alkaline solution, e.g., a 6 per cent. solution of caustic soda. After cooling, the caoutchouc is skimmed from the surface of the liquid and washed. —A. S.

XIV.—TANNING, LEATHER, GLUE, SIZE.

Skin Structure ; Microscopic Study of — H. Boulanger. Bull. Soc. d'Encouragement, 1905, 107, 51—54.

By using reflected light photo-micrographs of sections of tanned skin can be prepared, showing the fibres in their natural position. In the preparation of the sections, the leather is first washed in two or three changes of water, until the greater portion of the excess of tannin has been removed. The water is removed from the leather by treatment with successive portions of alcohol, and the dehydration is completed by means of absolute alcohol. The leather is then steeped in xylene for 8 hours, and afterwards embedded in a mixture of paraffin wax and tallow ; finally the section is cut, and is freed from fat by means of xylene or carbon bisulphide.

Photomicrographs prepared from sections of different parts of a hide tanned with oak bark, show that the fibres are larger and less entangled in the flanks and neck, and smaller and more compact in the butt.

The reason for the characteristic differences between leather tanned with vegetable materials and chrome-tanned leather is clearly seen by microscopic examination. The fibres of a chrome-tanned leather appear contracted and clean ; the spaces between the fibres are not filled up. These differences afford an explanation of the soft, pliable nature of chrome leather, its tendency to stretch and great strength as compared with the vegetable-tanned product.—M. C. L.

XVI.—SUGAR, STARCH, GUM, Etc.

Sugar Cane, Cane, Cane Sugar, etc.
E. F. Smith, *Centralb. Bakteriol.*, 1904, 13, 729.
Chem. Zeit. 1905, 29, Rep. 18.

IN 1893 Cobb gave a description of the so-called "A" disease of the Australian sugar cane, and concluded that it was due to a species of bacterium, *B. sacchari*, which he discovered in the yellow gum within the vascular fibres, but his attempts to infect healthy canes were unsuccessful. These bacteria were also described by Greig-Smith, and the author was able to grow them in pure cultivations without difficulty, and succeeded in inoculating healthy cane on green sugar cane with the culture, so as to produce all the symptoms of the Australian gum disease, and then produce a pure cultivation again from the characteristic gum in the cane. He designates the micro-organism *Erwinia sacchari* (Cobb). Two other varieties of sugar cane, *Antiochia*, No. 74, and the common purple cane, offered much greater resistance to infection, and culture media prepared from them were unsuitable for the growth of the *Erwinia*. The author attributed the greater suitability of the juice of the common green cane for the purpose to its smaller acidity. In practice Cobb's advice to plant varieties of sugar cane offering greater resistance to the disease has already given good results in the sugar plantations.

XVII.—BREWING, WINES, SPIRITS, Etc.

Starch, Saccharification of —, J. Moreau, *Ann. Soc. Roy. med. et nat. de Bruxelles*, 64; through *Woch. f. Bran.* 1905, 22, 37—39, 49—52, 72—75.

THE author has investigated and applied the method proposed by Bülow for the separation of the various conversion products of starch by precipitation by baryta water in aqueous and dilute alcoholic media. He determined the lower and upper limits of precipitation of the various products when the proportions of baryta hydroxide were varied, under standard conditions, the quantity of starch products and total volume being constant. In one series the precipitations were made in presence of water only, and in another series in presence of 10 per cent. of alcohol by volume. The progress and nature of the precipitations were determined from the iodine reactions of the filtrates. The results showed that amylopectin and erythropectin were precipitated in aqueous solutions, whilst achroodextrin and sugars were only precipitated in presence of alcohol, the limits of precipitation being sufficiently far apart to enable a complete separation of the different constituents to be effected by repeated fractional precipitation by barium hydroxide. When the products of the transformation of starch by malt-diastase, ptyalin, pancreas, blood-serum and mineral acids were subjected to fractional precipitation by the above method, it was found that in all cases, even in the very earliest stages of the reaction, all three forms of dextrins as well as sugar were present in the products. This observation affords a confirmation of Mittelaayer's theory of starch-conversion, namely,

that the starch molecule is immediately hydrolysed into all these products under the strain induced by hydrolytic agent, although it is possible that the subsequent hydrolysis of the dextrins first formed may take place in successive stages.

The author describes in detail the process by which prepared erythropectin and amylopectin in the 1st state, by repeated precipitation with baryta, starting from the dextrin of commerce. These two dextrins were finally obtained absolutely devoid of cupric reducing power, although the achroodextrin obstinately retained reducing sugar through many successive precipitations. The author, therefore, concludes that sugar, although it is intimately associated with dextrins, does not form an integral part of the dextrin molecule.—J. F. B.

Starch and Malt Grist: Heat Evolved on Wetting —, J. F. Hoffmann and M. Philippe, *Woch. f. Bran.* 1905, 22, 71—72.

EMSLÄNDER and Freundlich, in discussing the behaviour of solid surfaces when brought in contact with water, stated that when malt grist is mixed with water, the evolution of heat on hydration is such that the temperature of the mixture is the same whether the temperature of the water employed be 0° C. or 7°—9° C. The present authors attribute the evolution of heat to the production of enormous pressures by the penetration of the water into the capillary orifices of the granules. Capillary attraction is diminished when the temperature is increased, but the following experiments show that a decrease in capillarity with increased temperature is sufficient to make the temperature of the mixture independent of the initial temperature of the water. In a series, 200 grms. of dried starch, containing 4.8 per cent. of moisture, were mixed with 200 c.c. of water at temperatures increasing from 0° to 30° C. at intervals 10° C., the temperature of the starch being constant 15° C. The temperatures of the mixtures obtained showed differences of 4.5°—5.5° C. for every increment of 10° C. in the temperature of the water. A similar series of tests made with air-dry starch containing 14 per cent. of moisture, showed differences of about 6.5° in the temperatures of the mixtures for every 10° increment in the temperature of the water. The starch being more absorbent than the moist starch evolved more heat than the latter, but since the capillary phenomena predominate more strongly in the dry starch, they are more strongly affected by increased temperature, and the differences between the temperatures of the mixtures for an increase of 10° C. in the temperature of the water are consequently less. Other experiments were made with malt with varying temperatures of water and varying proportions, but the mixture never showed the same temperature.—J. F. B.

Lactase, the Enzyme which causes the Formation of Lactic Acid in Plant Cells. J. Stoklasa, *Ber. Dts. Botan. Ges.*, 1904, 22, 460—466. *Chem. Centr.*, 1905, 1, 265.

IN studying anaerobic respiration the author observed that more sugar was decomposed than corresponded to the amount of alcohol and carbon dioxide produced; that after protracted fermentation the acidity of the solution had increased; and that this acidity corresponded to the amount of lactic acid present. Further experiments showed that in the anaerobic respiration of sugar beets and other plants, under aseptic conditions, a certain amount of lactic acid is produced besides the chief products, alcohol and carbon dioxide. The enzyme which causes this formation of lactic acid was isolated in the crude condition. In solutions of dextrin containing 1—2 per cent. of toluene, it causes vigorous alcoholic fermentation and formation of lactic acid. The fermentation continues for more than 24 hours, hydrogen is evolved. The alcohol produced is oxidized by special enzymes to acetic acid. Formic acid is also formed, from which, by the separation of carbon dioxide, hydrogen is produced. This nascent hydrogen probably plays an important part in the assimilation of carbon dioxide in the cells containing chlorophyll.—A. S.

Mors; *Respiration and Alcoholic Fermentation of* — Kostytsehev. Centr.-Bl. f. Bakter. u. Parasitenk., 04, 13, 490—503, 577—589. Chem. Centr., 1905, 390.

The rule that true alcoholic fermentation can be recognised by the high value of the ratio $\frac{\text{CO}_2}{\text{O}_2}$, even with aeration, is true according to the author's results, not only of yeasts, but also of other micro-organisms, the mucors. The production of a large quantity of carbon dioxide by an organism when oxygen is excluded, however not a proof of alcoholic fermentation, as in the case of some organisms (e.g., *Mucor stolonifer*) carbon dioxide is produced very abundantly by intramolecular respiration. Intramolecular respiration can be distinguished from alcoholic fermentation by the fact that the amount representing the former has no maximum; the amount of carbon dioxide evolved decreases uniformly with the time. In the case of all the mucors examined (*stolonifer*, *mucedo*, and *racemosus*), there was observed, after continued withdrawal of oxygen, a considerable increase in the value of the ratio $\frac{\text{CO}_2}{\text{O}_2}$; this increase lasting, however, but for a short time. Warming the "Zymen" to 100° C. has no influence with regard to above coefficients. The dry preparation develops as much carbon dioxide with exclusion as with admission of oxygen. Thus a sharp line of distinction can be drawn between zymen and acetone preparations of the typical aerobes. *Mucor stolonifer* differs from the typical aerobes merely by its greater capacity of becoming accustomed to temporary anaerobic conditions; *M. racemosus* is a fermenting organism, and *M. mucedo* occupies a medium position between the oxidising and fermenting organisms.—A. S.

Film, Bottom Fermentation; Comparative Investigations — Four — *Forms of Growth on Solid Media; Giant Colonies.* H. Will. Z. ges. Branw. 1904, 27, 1—866 and 882—883. (See also this J., 1904, 450; 1905, 28, 71—75 and 93—97.)

The author has continued his studies on the forms of growth assumed by "giant colonies," i.e., colonies grown by sowing macroscopic quantities of cells on solid media. The present section deals with the forms of growth of the "giant colonies" developed by sowing film-cells of the second generation, as compared with those developed by cells of the fermentative sedimentary form of yeast film-cells of the first generation. The forms of the "giant colonies" during the whole period of their existence and their anatomical structure are described for sowings in cultures of various ages and varieties of yeast, (a) on 10 per cent. wort gelatin; (b) on 10 per cent. beer-gelatin.

The author next describes the forms of growth of colonies developed from the single cell elements of which the "giant colonies" grown from the various generations of yeasts are composed. Concluding with a general summary of the results of the whole investigation, the author states that the "giant colonies" on solid media and the film-formations on liquid media are equivalent and identical. This is proved by the history of the development of both forms and the physiological and morphological equivalence of the various cell elements composing both forms at various stages of their development. Both "giant colonies" on solid media and film-formations on liquids show two phases of developments, distinguished by distinct cell elements and in the case of "giant colonies" by definite forms of growth. In films, the two phases develop evenly, and are sharply defined; in both cases the cell elements characteristic of the two phases are produced similarly from different mother-cells which are equivalent both in films and "giant colonies." In spite of many similarities, the elongated, sausage-shaped cells characterising the two phases of development are morphologically and physiologically different.

The forms of growth assumed by "giant colonies" developed by sowing film-cells of the first generation coincide in general with the forms assumed during the first phase of their development by the "giant colonies"

developed by sowing cells of the fermentative form. Similarly the "giant colonies" developed from film-cells of the second generation correspond, especially on beer-gelatin media, with the second phase of the development of "giant colonies" from the fermentative form. The film generations are those which constitute the characteristic forms of the "giant colonies," and in which the morphological habit of the species of yeast is expressed. The form of growth is influenced by the nature of the nutrient and the nature of the solidifying medium, but the same law of development is followed in all cases. With "giant colonies" on wort-gelatin, the first phase of development predominates, whilst the second phase is only slightly developed since the gelatin generally liquefies before it is very pronounced. On beer-gelatin, the first phase is restricted and the second phase predominates. In film-formations the various cell-elements are mixed up without regularity, but in "giant colonies" the distribution of the various cell-elements follows a definite organisation, comprising "pith" layers (chains of elongated mycelial cells), "bark" layers (roundish and oval cells rich in oil) and "root hairs" consisting of the same elements as the "pith layers."—J. F. B.

Fermentation and Yeast Reproduction. A. Fernbach. Ann. de la Brass., 1904, 7, 553—555.

The individual cells in pitching yeast, store up reserve material, largely glycogen, from the wort, this reserve being afterwards consumed as required. These changes cause an alteration in the total weight of the yeast, but do not influence the number of cells present, this latter factor being determined by considerations of space. Each cell requires a certain amount of room for the normal discharge of its functions, failing which it dies off, so that where an excessive quantity of pitching yeast is used, there is no corresponding increase in the yeast crop. Consequently, the practice of stimulating sluggish fermentation by increasing the quantity of the pitching yeast is erroneous, since not only is reproduction checked, but fermentation is retarded as a result of the enfeebled condition of the yeast cells, which have been forced to draw on their own store of material. Moreover, the weakened cells have a low specific gravity and retard clarification; and lacking a full store of reserve material are unsuitable for stock yeast, even if they do not entirely lose their power after a short storage.—C. S.

Beers; Reddening of Pale Bottom-fermentation — on Pasteurisation. F. Schönfeld. Woch. f. Bran., 1905, 22, 64—67.

It is frequently observed that bottom-fermentation beers, especially the pale varieties, are darkened by the process of pasteurisation, and that in extreme cases they acquire a red colour approaching that of the Munich type of beer. The degree of darkening and the formation of the reddish tint vary greatly with different beers, and the composition of the beer is certainly the primary determining factor. The coloration is greatly exaggerated if the beer be pasteurised in open bottles. In exceptional instances pale beer may even darken perceptibly when kept in closed bottles without pasteurisation. A high proportion of carbon dioxide considerably reduces the liability to darkening. The production of the colour is probably brought about by albuminoids, e.g., by oxidising enzymes. The materials of which the bottles are composed also have an influence in inducing oxidation. Glass condenses water in the pores of its surface, and this water would contain dissolved oxygen, probably in a highly active condition capable of reacting through the medium of the oxydases. Glass also contains soluble alkalis which favour oxidation, and the darkening of the beer is especially marked in new bottles; it also frequently contains other bases which may act as oxygen carriers, such as manganese or chromium. The red colouring matter produced in the beer is probably an oxidation product of a phenolic body, perhaps tannin. Although certain bottles induce the coloration more strongly than others in beers liable to this defect, the same bottles have no perceptible influence on other beers, which are not sensitive to oxidation.—J. F. B.

Potato Mash; Distillation; Regulating It. S. J. J. Fermentation of —, W. Christel, Z. Saccharind., 1905, 28, 41.

POTATO mashes sometimes continue to ferment long after the time when fermentation should be finished, without, however, reaching their proper degree of attenuation. Prolongation of the time allowed for fermentation from 3 days to 4 or even 5 days, does not lead to much better results. In a case cited by the author, mashes made from potatoes with 5 per cent. of malted grain at the relatively low concentration of 19–20 Bx. were pitched at a temperature of 20° C. with pure yeast acidified by the usual lactic fermentation. After 3 days' fermentation, the mash was not ready for distillation, the density still being 1.5 Bx. with an acidity of 0.8 and carbon dioxide still coming off in considerable quantities. The presence of the gas retarded the speed of distillation and the alcohol showed a strength of only 87 per cent., as against 90–92 per cent. under normal conditions. This unsatisfactory fermentation was finally remedied by reducing the acidity of the yeast-mash, and stopping the acidification at an acidity of 1.8–2.2 instead of at 2.8–3.0. This caused a more intense primary fermentation, in consequence of which the artificial cooling of the mash in the fermentation tun must be more intense and prolonged. The results were, however, perfectly satisfactory; the mashes attenuated down to 0.5 Bx. with an acidity of 0.8–0.9, and the strength of the alcohol distilled rose again to 90–92 per cent.—J. F. B.

Apples and Cider; Chemical Composition of —. II. Composition of Cider as Determined by Dominant Fermentation with Pure Yeasts. W. B. Alwood, R. J. Davidson, and W. A. P. Moncre, U.S. Dept. Agric., Bureau of Chemistry, Bull. No. 88, 20–46.

APPLE juice was transferred straight from the presses into 50 gal. casks, and pitched as soon as possible with 1 pint per cask of cultures of pure yeast in vigorous condition. By this means it was easy to obtain fermentations under the dominant influence of the culture yeasts, without any previous sterilisation of the must. The yeasts employed were selected varieties from the best American and French cider and wine stocks. The fermentation and maturing in bottle were carefully studied and the finished ciders were tested by experts and by analysis. Results are tabulated for 15 samples of cider made from three different musts fermented by eight different varieties of pure yeast. They show remarkable uniformity as regards specific gravity, acidity and non-sugar extract, but the three musts were so nearly alike in their original composition that no general deductions can be drawn from this fact. On the other hand, there were striking differences in the proportions of alcohol; even in two samples prepared from the same must, with the total exhaustion of all the sugar, the proportions of alcohol produced by two different yeasts differed by as much as 1 per cent. Such differences greatly affect the other characters of the ciders, such as effervescence, aroma and flavour, which varied largely with the different yeasts. In all the samples the percentage of residual sugar was low, and in several the sugar was practically exhausted. No saccharose ever remains in a properly fermented cider, since it is readily inverted during primary fermentation. These ciders are compared with one fermented by "wild" fermentation and with several samples of commercial ciders. In these latter, fluctuations in the sugar contents from 0 to 13.56 per cent. are recorded, and in the alcohol from 0 to 6.87 per cent. This shows the extraordinarily wide limits between which the composition of this beverage is liable to vary. Many samples contained preservatives, since it is very difficult to bottle and retain more than 1.5 or 2 per cent. of sugar without either sterilisation or antiseptics.—J. F. B.

(A).—FOODS.

Cheese; Volatile Acids in —, and Biology of Cheese Ferments. O. Jensen. Centr.-Bl. f. Bakt. u. P. sitenk., 1904, 13, 161–170, 291–306, 428–439, 5527, 604–615, 687–705, 753–765. Chem. Ce., 1905, 1, 397–398.

SOME cheeses contain volatile acids that cannot have been produced by hydrolysis of the fat contained in the cheese; these acids occur most abundantly in the interior of the cheese. The morphological characters of the bacteria present in Emmenthaler cheese are described. The bacteria, with the possible exception of *Micrococcus liquefaciens*, are all true lactic acid ferments. Acetic acid was detected in all the cheeses examined, as also formic acid, but frequently only in traces; both are produced by all the cheese ferments. In those cheeses the ripening of which is effected mainly by mould fungi, the volatile acids present, besides those produced by hydrolysis of the cheese-fat, consist of only small quantities of acetic and formic acids. In these cases the mould fungi cause only hydrolysis, not fermentation of the fat. In all other kinds of cheese propionic acid is present in frequently in considerable amounts. As the odour of a volatile fatty acid is stronger the higher the molecular weight, it follows that in most cheeses the volatile acids produced by hydrolysis of the cheese-fat, have a much greater influence on the aroma than the volatile acids formed from other constituents: capric, caprylic, caproic acids are of most importance in this respect, then valeric and butyric acids. Cheeses in which hydrolysis of the fat has been considerable, nearly always contain ammonia. Certain cheeses have characteristic aromas produced mainly by special constituents, i.e., sweetish amino-acids in Emmenthaler cheese, butyric acid esters of very sharp taste in Roquefort, certain products of putrefaction in Limburger, and the aromatic constituents of sweet-scented clover, *Melilotus coerula*, in Schabzieger cheese.

The action of pepsin, added along with the rennet, on paracasein was examined, and it was found that the latter was strongly attacked, the action being moreover considerably increased in presence of *Bact. lactis acidii*. In *casei limburgensis*, when it acts alone on casein and pepsin, forms only primary albumoses; pepsin in presence of lactic acid ferments, forms also secondary albumoses and peptones.—A. S.

ENGLISH PATENTS.

Milk and Milk-like Products; Manufacture of —. [Digested] —, J. R. Hatmaker, Paris. Eng. Pat. 3531, Feb. 12, 1904.

MILK is treated with a digestive agent such as pepsin, pancreatin, or it may be subjected to the hydrolytic action of superheated steam. The milk is then dried.

suitable quantity of cream may be added to the digested milk, and also, before or after drying, a certain amount of milk sugar, in order to make the product a substitute for human milk. Milk may be used, of which the natural proportions of the constituents have been increased or diminished. —W. P. S.

Milk Preparation: Process for Making an easily Digestible, — free from Germs. S. Székely and E. Kovács, Buda-pesth. Eng. Pat. 25,624, Nov. 24, 1904.

STERILIZED milk is heated to a temperature below 67° C., and the casein precipitated by means of carbon dioxide under high pressure, in a suitable pressure vessel. The curd is then carefully run off from the spongy mass of whey (rejecting the first turbid portion), the pressure of carbon dioxide gas serving to force the whey out of the vessel. If the casein is allowed to leave the vessel, the whey will be approximately sterile. This whey is mixed with pasteurized milk or cream to form a food for infants. From 0.2 per cent. of sterilised sugar may also be added. —W. P. S.

Food Stuffs and the like; Method of Sterilising — J. Proisz, Copenhagen. Eng. Pat. 22,927, Oct. 25, 1904. Under Internat. Conv., Oct. 28, 1903.

THE process is one for sterilising the foods by means of ultraviolet light rays, and is chiefly applicable to liquids, though solids in the form of threads, scales or shavings, may also be treated. In the case of liquids, these may be passed into a centrifugal apparatus where they are in the shape of a thin film on the corrugated walls of the drum. At the centre of the drum are placed one or more arc or spark lights, preferably uncovered. The treated liquid is withdrawn from the top of the drum; the stationary vessel may be employed, the liquid being sprayed on to the walls by a sprinkling arrangement or suitable spreader. The chamber may be partly filled with air, or a current of nitrogen, carbon dioxide, hydrogen, steam, &c., can be passed through it, if desired. —W. P. S.

Food Products containing Iron; Process for Preparing — C. Aufberg, Wiesbaden, Germany. Eng. Pat. 27,266, Dec. 14, 1904.

COMPOUND of iron and cane-sugar or other carbohydrate added to the food. This compound is prepared by mixing together 555 grms. of sugar and 1900 grms. of dissolved iron solution ("liquid iron oxychloride") of sp. gr. 1.05. To this is added 120 grms. of "soda lye" of sp. gr. 1.172. The resulting precipitate is re-dissolved by constant stirring and heating, and the solution then concentrated to a weight of 1000 grms. It contains 6.6 per cent. of metallic iron, but if completely dried, the pulverulent mass will contain 10 per cent. of iron. The preparation may be added to dough (for bread, biscuit, cake, &c.), to soups, soup meal, feeding meal and the like, in such quantity that the iron content of these is increased to 0.25 or even 0.1 per cent. —W. P. S.

(B.)—SANITATION; WATER PURIFICATION.

Water Supplies; New Method of Purifying — G. T. Moore. Amer. J. Pharm., 1904, 76, 553—564.

During the last two years copper sulphate has been extensively used by the water companies in many parts of the United States to destroy the blue-green algae (pond scum) that form on the reservoirs and impart an offensive odour and taste to the water, or, in some instances, the water in the reservoir at Winchester, N.Y., which was constructed in 1890, had become so offensive from this cause as to render its use for any purpose intolerable. Filtration and aeration effected no improvement, and eventually the addition of copper

sulphate in the proportion of 1 part to 5,000,000 was tried, with the result that after three days the odour had disappeared and the water was perfectly clear. Another similar treatment was made in 1901, but with this exception no copper has been added since the original addition in June, 1903. Similar experiments were made on water-cress beds in the Southern States, where it had been found that after the cress had been cut, a mat of algae would form in sufficient thickness to prevent to a large extent the new growth of the plants. Copper sulphate added to the water in the proportion of 1 part to 50,000,000 entirely prevented the algal growth without in any way injuring the cress, and since the first application in 1901 it has only been necessary to repeat this treatment once a year. As regards the influence of the copper on bacteria, experiments showed that the micro-organisms found in sewage were destroyed to the extent of 95 per cent. by one treatment of the water containing them. C. A. M.

Water; Copper Treatment of — H. Kraemer. Amer. J. Pharm., 1904, 76, 574—581.

THE author's explanation of why minute quantities of copper sulphate, such as 1 part to 5 or 50 millions of water should be able to kill algae without injuring higher plants is that the former being unicellular, are entirely surrounded by the copper solution, and the whole of their functions simultaneously affected. It has been shown by Moore that typhoid and cholera organisms are destroyed by copper sulphate solutions (1 part in 100,000) within 3 to 4 hours. In the author's experiments with ordinary tap water, copper sulphate was used in the proportion of 1 part to 100,000, and 1 part to 1,000,000, the solutions being kept for 48 hours at the ordinary temperature. It was found that in the first case the total number of micro-organisms had been reduced by 99 per cent. and in the second case by 90 per cent. Further experiments to determine the action of metallic copper on colon and typhoid bacilli showed that both were completely destroyed within four hours at the ordinary temperature, by immersing clean copper foil in the water containing them. Colloidal copper also effected complete destruction of the micro-organisms. For household purification the author recommends the use of strips of copper about 3½ sq. in. to each quart immersed in the water for six to eight hours.—C. A. M.

XIX.—PAPER, PASTEBOARD, Etc.

Printing Papers; Absorbent Properties of — P. Klemm. Wochenbl. f. Papierfab., 1905, 36, 18—19.

THE absorbent properties of paper for the oily medium of printers' ink do not correspond exactly with the absorption of aqueous inks; e.g., certain soft-sized papers absorb the oil of printers' ink no more readily than hard-sized papers. The quantity and ink-resisting power of rosin sizing have no influence on the absorbent properties of the paper towards oil, since rosin is easily wetted by oil. Gelatin hinders the absorption of the oil, as is shown in the case of coated papers, but mineral matters are favourable. The structure of the paper, as determined by the nature of the fibres and their behaviour on beating,

is also an important factor. The denser the sheet, the less oil-absorbent is the paper, since the fibres, standing itself resists oil but not water; the absorptive powers of different papers towards oil do not vary so widely as towards water. When paper is printed, the oil-varnish medium distributes itself between the pigment and the paper, according to the relative absorptive powers of each; if the paper be too absorbent the medium may be withdrawn from the pigment to such an extent that the latter rubs off. This effect will vary according to the thickness of the oil-varnish; with very absorbent papers it may be necessary to employ a thicker varnish, or else a certain excess of varnish which will fix the pigment after the paper has absorbed as much as it is capable of. The elasticity of the paper is of greater importance than the porosity on which the absorptive power depends. It is desirable that any inequalities and pores in the sheet should be capable of being evened up by the pressure during printing; the good printing qualities of coated "art" papers are due to the uniformity of the surface, and their deficient absorptive power is of little importance. One great advantage of a highly porous paper is that the access of air is facilitated and the varnish dries more rapidly; this is of greater importance than a high absorptive power. A drawback of high porosity, however, is the liability of the oil to penetrate to the back of the paper, and show the printing on the reverse side.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

Monazite Earths. W. Feit and K. Pyzbylla. Z. anorg. Chem., 1905, 43, 202–214.

A DETAILED account is given of the separation of the earths contained in monazite residues, the method being based upon the fractional crystallisation of the magnesium

double nitrates, in neutral, or very slightly alkaline solution. The volumetric determination of the atomic weight of the fractions is recommended as a speedy and convenient method of following the progress of the separations. About 0.5 gm. of the earth, which has been ignited until constant in weight, is placed in a beaker-tena glass, along with a little water and a measured quantity of N₂O sulphuric acid, and warmed until dissolved. The excess of acid is then determined by cautious titration with sodium hydroxide solution, methyl orange being used as indicator. With care, the atomic weight found should be correct within 0.3.—H. B.

Nitro-Derivatives: Preparation of Organic —. Matnschek. Chem.-Zeit., 1905, 29, 115.

IN preparing magnesium or zinc nitrite by his process (this J., 1902, 705) the author detected an ethereal odor in the alcoholic filtrate; and on heating the alcoholic mixture of sodium nitrite and magnesium sulphate under a reflux condenser for some time, ethyl nitrite was formed. The reaction doubtless depends on the hydrolysis of the magnesium nitrite—

the nitric oxide escapes, while the peroxide at the moment of formation reacts with the alcohol to form ethyl nitrite. Many other metallic salts mixed with sodium nitrite react similarly, particularly ferric chloride; with this mixture nitro- (and in some cases also nitroso-) derivatives of phenols, and of aromatic amines and aldehydes can be prepared. Even benzene is partially converted into nitrobenzene; the process may prove to be of service industrially. Nitrosobenzene appears to be an intermediate product.—J. T. D.

Quinine Hydrochloride, Neutral — [Composition of the Crystallised from Alcohol]. C. Erba. J. Pharm. Chim., 1904, 20, 550.

THE author finds that neutral quinine hydrochloride as crystallised from 95 per cent. alcohol, contains 1 π each of alcohol and of water of crystallisation, responding to the formula $\text{C}_{20}\text{H}_{21}\text{N}_3\text{O}_2 \cdot 2\text{HCl} + \text{C}_2\text{H}_5\text{O} + \text{H}_2\text{O}$ and 1 to the salt containing $\frac{1}{2}$ mols. of water of crystallisation as stated by Carette (this J., 1904, 1041).—J. O. B.

Eucalyptus Polybractea: Essential Oil of —. J. Umney and C. T. Bennett. Pharm. J. 1905, 74, 143

THE oil of the Blue Mallee, *Eucalyptus polybractea* is found to have the following characters. Sp. gr. 0.929; α_D^{20} = Eucalyptol content, by Scammell's process, 79 to 80 per cent. Since the oil contains no appreciable amount of aldehydic constituent, it is free from any irritating action when inhaled. It is considered to be at least equal to oil of *E. globulus* in medicinal value.—J. O. B.

Criferous Compounds or Perfumes; Manufacture of —, E. Knoevenagel, Heidelberg, Germany. Eng. Pat. 23,578, Nov. 1, 1904. Under Internat. Conv., Oct. 10, 1903.

Compounds of the citral series, such as are obtained by condensation of citral with acetone, acetylacetone, &c. are treated with hydrogen halogen acids, and the halide compounds thus formed are treated with alkali to split off the halogen acid, when isomerisation takes place, odoriferous compounds being produced. For example, 2 parts of a 20 per cent. solution of hydrobromic acid in glacial acetic acid are added to one part of pseudocitral, and the mixture is allowed to stand. The acid is neutralised, and the hydrobromide, which crystallises, is decomposed by boiling with dilute sodium carbonate solution. (Compare Fr. Pat. 335,380 of 1903; this J., 1904, 204.)—T. F. B.

UNITED STATES PATENT.

Morphine Compound [Codeine Bromomethylate] and Process of Making same. R. Pschorr, Assignor to the Firm of J. D. Riedel, Berlin. U.S. Pat. 780,619, Jan. 24, 1905.

A alcoholic solution of 1 mol. of morphine, 1 mol. of dihydroxide and 2 mols. of methyl bromide is heated several hours at 50° to 60° C. in a closed receptacle; a crystalline paste, which separates on cooling, is extracted with alcohol, and the solution evaporated. By crystallising the residue from hot water, pure codeine bromomethylate, $C_{18}H_{21}NO_3(BrCH_3)$, is obtained, of m.p. 261° C. It is easily soluble in water, moderately soluble in warm methyl alcohol, sparingly soluble in acetone, and insoluble in ether or benzene. It yields a crystalline picrate, and gives a yellowish precipitate with mercuric chloride and a flesh-coloured precipitate with phosphomolybdic acid. It is decomposed by concentrated sulphuric acid, hydrobromic acid being evolved.—T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Emulsions made with Adhesive Substance, Lippert-Cramer. Phot. Kor., 1905, 42, 12. Chem.-Zeit., 1905, 29, Rep., 10.

AN emulsion of mercuric iodide in gum is very much more sensitive to light than a gelatin mercuric iodide emulsion; in the former case, the mercuric iodide is obtained in the red form, in the latter, in the yellow. A gum arabic silver iodide emulsion is similarly found to be 60 to 100 times more sensitive to light than a gelatin silver iodide one. The grains of the former emulsion are very much coarser than those of the gelatin emulsion. "Ripening" at 50° C. for some hours does not diminish the difference in sensitiveness. On the other hand, a gelatin silver bromide emulsion is four or five times more sensitive to light than a gum silver bromide emulsion, but a gum silver chloride emulsion is two to three times more sensitive than a gelatin emulsion. Casein silver iodide emulsions are about $\frac{1}{200}$ th part as sensitive as gelatin silver iodide. Mercurous iodide, when emulsified in gelatin, is 3–4 times more sensitive than when emulsified in gum. When emulsified in albumin, mercuric iodide is obtained in the yellow form; in dextrin emulsions the red modification is formed if the mercuric chloride be added first, but the yellow, if the soluble iodide be introduced before the mercuric salt.—T. F. B.

Panchromatic Plates; Bathing Formula for —, Valenta. Liesegang's Almanac. Brit. J. Phot., 1905, 52, 89.

A TREATMENT of dry plates with a solution of Ethyl Violet, Erythrosin, and monobromofluorescein is recommended for producing panchromatic plates of even sensitiveness throughout the spectrum. A mixture is made of Ethyl Violet solution (0.02 per cent.), 10 parts; Erythrosin solution (0.2 per cent.), 2 parts; monobromofluorescein solution (0.02 per cent.), 3 parts. The plate is bathed for three minutes in a solution containing 15 parts of the above solution, and two parts of ammonia in 500 parts of water.—T. F. B.

Developing Agents; Solubility of — [in Water and Sodium Sulphite Solution]. Gravier. Brit. J. Phot., 1905, 52, 90.

THE following table of solubilities is given for various developers in common use:—

	Solubility in 100 parts of:		
	Water at 15° C.	Water at 45° C.	10 per cent. sodium sulphite solution at 15° C.
Adarol	100	over 100	65
Amidol	3.0	33	28
Eikonogen	7.8	17	4
Glycin	0	0.2	trace
Quinol			
(Hydroquinone)	6	14	4
Metol	5	9	2
Ortol	36	52	0.75
2-Aminophenol hydrochloride	7.4	11	0.8
Pyrogallol	59	over 100	59

—T. F. B.

Toning by Means of Lead and Cobalt; New Method of —, A. and L. Lumière and A. Seyewetz. Monit. Scient., 1905, 19, 104–105.

SILVER images may be toned a brilliant green by bleaching in a solution made up of water, 1 litre; potassium ferricyanide, 60 grms., and lead nitrate, 40 grms., washing, and then immersing for a few minutes in a solution of cobalt chloride, 100 grms., hydrochloric acid, 300 grms., water, 1 litre. In the first bleaching, formation of double silver lead ferrocyanide occurs, but is not complete, the image having a composition intermediate between those repre-

sented by $\text{Pb}_3\text{Ag}_2\text{Fe}_{10}(\text{CN})_{12}$ and $\text{Pb}_2\text{Fe}(\text{CN})_6$. On immersion in the cobalt chloride solution, part of the silver is substituted by cobalt, with the result that a cobaltous silver-ferrocyanide is formed, the composition of which lies between those represented by the formulae $\text{Co}_2\text{Ag}_2\text{PbFe}_{10}(\text{CN})_{12}$ and $\text{Co}_2\text{Fe}(\text{CN})_6$.—T. F. B.

Toning Photographic Images Blue by a New and Simple Method of —. R. Namas. *Monit. Scient.*, 1905, 19, 106.

THE blue coloration produced by the reduction of molybdic acid solutions can be utilised for toning silver bromide prints. A solution of 10 grms. of molybdic acid in 50 c.c. of ammonia (sp. gr. 0.940) is added to 100 c.c. of dilute nitric acid (1:1). 50 c.c. of this solution and 10 grms. of potassium metasulphite are dissolved in 150 c.c. of water, and the prints immersed until the desired blue tone is obtained. The toned image contains no silver salts; in fact, the silver may be dissolved out, leaving a rather faint blue image, hence it is concluded that the silver only aids in the reduction of the molybdic acid. This method has the disadvantage that pure whites are difficult to obtain; treatment with acids has no beneficial effect, whilst treatment with alkali solutions destroys the blue image.—T. F. B.

ENGLISH PATENTS.

Lighting (Flashlights) for Photographic Purposes; Powders or Compositions for use in Artificial. — G. Krebs, Offenbach-on-Maine, Germany. Eng. Pat. 27,267, Dec. 14, 1904.

"FLASHLIGHT powders" for photographic purposes, which burn with practically no smoke, are obtained by mixing finely powdered aluminium or magnesium, or a mixture of both, with an equal weight of chrome alum, potash alum, or other alum, or with copper sulphate, or the sulphate of an alkali or alkaline earth, or of cerium, thorium, iridium or cesium. By mixing these flashlight powders with about 10 per cent. of alkaline earth oxides or carbonates, or with a silicate, slow burning powders are obtained. (Compare Fr. Pat. 337,901 of 1903; this J., 1904, 560.)—T. F. B.

Lighting especially for Photographic Purposes; Powders or Compositions for use in Artificial. — G. Krebs, Offenbach-on-Maine, Germany. Eng. Pat. 27,268, Dec. 14, 1904.

SEE Fr. Pat. 337,901 of 1903; this J., 1904, 560.—T. F. B.

Light for Photographic and other Purposes; Flash Powder for Producing Artificial. — H. Lüttke, P. Arndt, and E. L. Löwenhard, Wand-bek, Germany. Eng. Pat. 27,465, Dec. 16, 1904.

IRON or copper compounds, which act as oxygen carriers, are added to magnesium or aluminium, or a mixture of these, to produce flash light powders. For example, a suitable mixture consists of magnesium, 100 parts; aluminium, 50 parts; ferric oxide, 30 parts; copper carbonate, 20 parts, and magnesium sulphate, 5 parts. —T. F. B.

APPARATUS, Etc.

Micro-Balance; Some Experiences in the Use of the. — O. Brill. *Ber.*, 1905, 38, 140—146. (See this J., 1904, 925.)

IT was found that the variation of the zero point was due principally to the hygroscopic character of the water-glass cement used for fastening the beam to the quartz fibre. By using sealing-wax or a celluloid cement instead of water-glass, much better results were obtained. The author also gives several other details with regard to the construction and mounting of the balance if very accurate results are desired.—A. S.

ENGLISH PATENT.

Pyrometers; Impts. in. — C. Fery and Comp. pour la Fabric. des Compt. et Matériel d'Usines à Gaz. Paris. Eng. Pat. 18,382, Aug. 24, 1904.

THE inventors claim the combination of an optical sight apparatus containing two prisms having an aperture opposite the junction of a thermo-couple, with a galvanometer and recording apparatus. The prisms distort the image of the object sighted, unless it is directly in the plane of the aperture. When in this position, the heat ray concentrated upon the junction of the thermo-couple by the mirror, actuate a moving coil galvanometer. Clockwork mechanism is so arranged that an advancing bar of paper is pressed at regular intervals against a pen held in an arm attached to the coil of the galvanometer, and series of marks or dots forming the record, is obtained. The galvanometer can be cut out of circuit by a commutator, whilst the pen is being dipped into the ink.—W. H.

INORGANIC—QUALITATIVE.

Portland Cement; Detection of Free Lime. — G. Baikoff. *Zement.*, 1904; *Tonind. Zeit.*, 1904, 2, 1713—1715, 1747—1749.

ON applying an alcoholic solution of phenolphthalein to slag-cement, Roman cement, and Portland cement, the author found the first named gave a red coloration immediately, due to the presence of free calcium hydroxide; the second after a little while, but with the Portland cement no colour change at all occurred, either in the cement or in the solution. From this difference it is assumed that Roman cement contains calcium alumina which undergoes hydrolysis, whilst in Portland cement the lime is combined as silicate. Further,—it was found that Portland cement decolorised the alcoholic phenolphthalein stained red by calcium hydroxide, the color being restored by re-exposure to hydroxide after filtration. This behaviour indicates the possession by anhydrous Portland cement of the power of absorbing calcium hydroxide, thus reversing the process occurring when the same cement is mixed with water. This double character of Portland cement is attributed to the presence of the intimate mixture of basic silicate and puzzolane, of which the cement is composed. Owing to the high fusing point of the silicate (over 1700° C.), it could not be formed at the ordinary kiln temperature (1500° C.) without a flux, such as is afforded by the presence of oxides of alumina, iron and alkalis in the clay. The basic silicate is slightly less soluble than lime; and being formed in the presence of an excess of lime is strongly basic, and resembles blast-furnace slag. Finally, a sample of Portland cement which failed to pass the boiling test was proved to contain free calcium oxide, by the coloration given with aqueous alcoholic phenolphthalein.—C. S.

INORGANIC—QUANTITATIVE.

Normal Hydrochloric Acid; Table for the Preparation of. — according to Specific Gravity. F. W. Küstner and S. Münch. *Ber.*, 1905, 38, 150—152.

PURE concentrated commercial hydrochloric acid, mixed with about twice its volume of water, and the specific gravity of the diluted acid is determined at 18° C. by weighing.

stoppered Erlenmeyer flask, the amount delivered by 0.00 c.c.-pipette, the exact "water-value" of which has been previously determined in a similar manner, the following table is shown the number of c.c. of hydrochloric acid of sp. gr. between 1.05 and 1.14, which yield $N/1$ acid when diluted to 1 litre with distilled water.

Table for the Preparation of $N/1$ Hydrochloric Acid.

Sp. gr. of acid at 18° C.	c.c. of acid to be measured off and diluted to 1 litre.	Difference per 0.0001 of sp. gr.	Log.
1.0500	343.3	0.64	8062
550	311.3	0.54	7324
600	284.3	0.46	6628
650	261.3	0.398	5999
700	241.4	0.344	5566
750	224.2	0.296	4713
800	209.4	0.260	4150
850	196.4	0.230	3617
900	184.9	0.206	3139
950	174.6	0.184	2648
1.1000	165.4	0.165	2175
050	157.15	0.150	1761
100	149.65	0.138	1399
150	142.75	0.126	1004
200	136.45	0.116	0645
250	130.65	0.109	0374
300	125.20	0.103	0128
350	120.05	0.098	9912
1.1400	115.15		

The figures in col. 3 give the difference in the number of to be measured off for each 0.0001 difference of sp. gr., the figures in col. 4 are the logarithms of the numbers col. 3. As an example, to prepare $N/1$ acid from acid sp. gr. 1.1037, $165.4 - 37 \times 0.165 = 159.3$ c.c. must be added to 1 litre. This method of preparing standard is specially suitable in works, where large quantities required.—A. S.

Kali Heptamolybdates; New Iodometric Method for Determination of —. B. Glassmann. Ber., 1905, 38, 193—4.

KALI heptamolybdates may be determined by ascertaining the amount of iodine liberated on boiling with solution of potassium iodide and iodate. 0.2—0.3 gram. the heptamolybdate is placed in the distilling flask of Bunsen's iodine apparatus, together with 0.5 gram. of potassium iodide, and 0.1 gram. of potassium iodate. Still water is added, and the mixture distilled. The line is collected in the usual way, and titrated with standard thiosulphate. The author proposes to adapt the method to the determination of polytungstates.

—B. J. S.

Copper, Tin, Antimony and Lead; Separation and Determination of —. Application to the Determination of Antimony in Bronzes. M. Dinan. Monit. Scient., 1905, 19, 92—94.

500 grm. of the alloy is heated with nitric acid, the solution is evaporated, the residue treated with dilute nitric acid and the solution filtered; the precipitate, which contains the antimony and tin, with a small quantity of copper and lead, is boiled with 7 grms. of oxalic acid and grms. of ammonium oxalate in 150 c.c. of water for 45 minutes and diluted to 250 c.c.; a current of hydrogen sulphide is then passed through the solution for $2\frac{1}{2}$ to 3 hours (the temperature being kept at 90°—95° C.). After filtering, the solution is boiled, concentrated and electrolysed in presence of 10 grms. of oxalic acid, at 65°—70° C., with a current of 0.5 to 0.7 ampère per sq. decim., at an E.M.F. of 3.5 to 4 volts. The deposited tin is dried and weighed. The precipitate of sulphides is heated with potassium hydroxide solution, the liquor decanted, and the precipitate washed with hot water free from air. The potassium hydroxide should not be used in great excess. The antimony solution may be electrolysed, after adding sodium sulphide, at 50°—60° C., using a current density of 1 ampère per sq. decim., at 1.5 to 2

volts., or it may be treated by Thompson's method (converting into pentachloride, adding excess of potassium iodide, and determining the iodine by means of thio-sulphate). The precipitate of copper and lead sulphides is immerged, dissolved in nitric acid, and added to the solution obtained after the first treatment with nitric acid. Excess of sulphuric acid is added and the solution evaporated until evolution of sulphur trioxide commences, when it is diluted and filtered, and the lead sulphate washed with 10 per cent. sulphuric acid. The filtrate is electrolysed in the cold, in presence of nitric acid, with a current of 0.5 to 0.7 ampère per sq. decim., at an E.M.F. of 3.5 to 4 volts.

This method can be extended to the analysis of bronzes containing antimony, the method of treatment being the same, with the addition that the zinc is determined in the usual way in the solution from which the copper has been removed by electrolysis.—T. F. B.

Phosphorus in Bronzes; Determination of —. M. Dinan. Monit. Scient., 1905, 19, 91.

THE bronze is treated with nitric acid, the precipitate (which contains the phosphorus as stannic phosphate) is dissolved in ammonium oxalate and oxalic acid, and the solution electrolysed as indicated in the preceding abstract. The solution, which becomes alkaline when electrolysis is complete, contains the phosphorus as ammonium phosphate, which may be determined by precipitation with molybdic acid.—T. F. B.

Muntz's Metal; Analysis of — by Electrolysis, and Some Notes on the Electrolytic Properties of this Alloy. J. G. A. Rhodin. Paper read before Faraday Soc., Jan. 30, 1905.

THE author has devised a compact arrangement of electrolytic apparatus for the gravimetric determination of copper in copper-zinc alloys on a large scale. Some 25 separate analyses are simultaneously carried out, and by employing a higher current density during the day than during the night, the plant can deal with 75 samples in the 24 hours. The arrangement of electrodes is shown in Fig. 1., the smaller anode being concentric with the

FIG. 1.

cathode when both are placed in a beaker which serves to contain the solution of the alloy. The gauze of the electrodes is made of platinum wire, No. 36, B.W.G., 90 meshes to the in., and is supported by a frame of stouter platinum wire. With these electrodes, currents of 0.5 or 2.0 ampères are employed, in the former case the deposition takes 12 to 15 hours, in the latter it is complete in three hours. Five electrolytic vessels are connected in

parallel, all with their own resistances, to a pair of commutator cells; the several pairs of commutator cells

charged in series. This arrangement is shown in Fig. 2. A mean probable error of 0.07 per cent. is claimed. —R. S. H.

Thorium Dioxide: Precipitation of and Separation of from Cerium, Lanthanum and Didymium Oxides by means of Organic Acids. A. Kolb and H. Ahle. *Z. angew. Chem.*, 1905, 18, 92-93.

CINNAIC, benzoic, salicylic, and *m*-nitrobenzoic acids, particularly the last-named, have been found suitable for the separation of thorium from ceria, lanthana and didymia, by precipitation. To the neutralised solution containing the thorium salt there is added, hot or cold, an aqueous solution of *m*-nitrobenzoic acid, and then a small quantity of a solution of *m*-nitrobenzoate of aniline to prevent the liberation of free mineral acid, the thorium being thrown down quantitatively as a white, flocculent precipitate which can be collected, dried, and converted into thorium dioxide by ignition. Lanthanum, didymium and cerous salts give no precipitate under these conditions; but as ceric salts give a yellow precipitate, it is necessary, in separating thorium from other earths, first to reduce any ceric salts which may be present to the cerous condition by means of sulphuretted hydrogen. If small proportions only of other earths are present, a single precipitation yields the thorium in a pure state; in other cases the thorium is obtained in a pure state by a second precipitation. The process may be used with good results in determining the thorium in monazite sand. —H. B.

ORGANIC—QUALITATIVE.

Eryogenin [m-Benzaminosaccharazob]: New Colour Reactions of —. G. Péguier. *Ann. Chim. anal. appl.*, 9, 456-457. *Chem. Centr.*, 1905, I, 106.

ERYOGENIN gives a chestnut-brown colour with potassium permanganate. When a few crystals of eryogenin are heated in a test-tube, they become coloured dark brown, and ammoniacal vapours are evolved. With a drop of sulphuric acid and of potassium bichromate solution, the crystals are coloured red. (See also this J., 1903, 712.) —A. S.

ORGANIC—QUANTITATIVE.

Coke and Volatile Matter yielded by Coals: Determination in a Platinum Crucible, of the Percentage of —. G. Arth. *Bull. Soc. Chim.*, 1905, 33, 127-129.

THE percentage of coke obtainable from a coal by the method of Muck is not only larger than that yielded in practical manufacture, but varies with the size of the crucible employed. These errors are mainly due to the fact that the temperature, especially at the bottom of the

crucible, is too low. The author prefers to heat with ordinary laboratory blowpipe, giving a steady flame 28-30 cm. long. The crucible, which is placed about 10 cm. above the orifice of the blowpipe, is furnished with a lid into which it fits to a depth of 5-6 mm. The lid constructed with a central platinum tube, 15 mm. long and 4-5 mm. in diameter, with a loose cap. The cap on the tube when the heating is commenced, but is removed as soon as a luminous flame appears, and is replaced when the flame is on the point of disappearing. The heating of the crucible may be prolonged for more than a minute after the disappearance of the flame, without any error being caused. The results are 1-2.25 per cent. lower than with a Bunsen burner, and the coke contains about 1 per cent. less hydrogen. —M. J. S.

Petroleum from Boryslaw: Determination of Impurity in Crude —. M. Wielezyski. *Chem.-Zeit.*, 1905, 29, 77.

ON account of its high paraffin content, crude Boryslaw petroleum contains considerable quantities of water and dirt, which it is very difficult to remove. The method usually adopted for the determination of these impurities is to add to the crude oil an equal volume of benzene, allow the mixture to stand in a graduated vessel for hours at a temperature of 45°-50° C.; the volume of the emulsion which separates is a measure of the amount of impurity. An error arises in this method due to the loss of water which necessarily occurs at the temperature employed. It is therefore proposed to accelerate the separation of the emulsion precipitated by the benzene by a short treatment in a centrifugal machine; after 5 or 10 minutes the separation is said to be complete. This method gives results from 0.4 to 2.0 per cent. higher than the usual method. —T. F. B.

Mineral Oils: Determining the Flashing Point of —. W. Herbig. *Chem. Rev. Fett- u. Harz.-Ind.*, 1905, 12, 26-30.

IN comparing the results of flashing point determination of heavy mineral oils by the Pensky-Martens and open cup tests (Kissling modification), the author found differences of 10-14° C. in ten experiments, and 15°-25° in seven others, the oil vapours being carried away by the current set up by the heating flame for the open cup, and thus giving higher results than the closed cup method. The discrepancy can, however, be obviated by covering the open cup with a fireclay lid, containing central orifice 15 mm. in diameter, the results furnished by this modification agreeing with the Pensky-Martens test to within about 4°. It is recommended that when the Pensky-Martens test is to be applied, a preliminary test should be performed with the semi-closed cup, in order to obtain an approximate idea of the flashing point since the test is more easily applied and saves the time spent in cleaning the Pensky-Martens apparatus. —C. S.

Dinitrocaoutchouc; Weber's —. C. Harries. *XIII C.*, page 203.

Caoutchouc; Nitrosides of —, and their Application in the Analysis of Raw Rubber and Rubber Goods. Alexander. *XIII C.*, page 203.

Methyl-Pentosans in Presence of Pentosans; Determination of —. W. B. Ellett and B. Tollens. *Z. V. deutsch. Zuckerind.*, 1905, Jan., 19-30.

WHEN materials containing both pentosans and methyl pentosans are distilled with hydrochloric acid, sp. gr. 1.06 the distillates contain both furfural and methylfurfural which are precipitated and weighed together as phloroglucides. The authors have determined the weight of methylfurfural phloroglucide obtained by the distillation of pure rhamnose under standard conditions [Kröber method]. The end point of distillation is recognised by the fact that a few drops of distillate containing methylfurfural give a yellowish-red coloration with one drop of a solution of phloroglucinol in hydrochloric acid sp. gr. 1.06. The results are calculated from the formula $Rhamnose = Ph.1.65 - Ph.21.84 + 0.01$, where Ph. = weight

phloroglucide in grms. When weighed quantities of glucose and rhamnose were distilled together, the phloroglucides were separated by extraction with 5 per cent. alcohol, in which the furfural compound is sparingly soluble. The glucose crucible contains a dried and weighed mixture of phloroglucides is placed in a small beaker; 15–20 c.c. of alcohol are introduced into the crucible, and the beaker is heated on the water-bath for 10 minutes at about 60° C. The alcohol is then drawn off by aid of the pump and the extraction is repeated 2 or 3 times more, in the same manner; the residue is then dried for 2 hours and calculated as pentose by Kröber's tables.—J. F. B.

Alcohol in Formaldehyde: Determination of ——. Gnehm and F. Kautler. *Z. angew. Chem.*, 1905, 48, 3–94.

BERGER has stated (this J., 1904, 914) that the "Berger" process (this J., 1904, 626) for the determination of methyl alcohol in formaldehyde gives results which are low. If, however, the quantity of sodium sulphate used be increased from 90 grms. (as originally employed) to 110 grms., the results are satisfactory even with formaldehyde of high strength. The occurrence of an appreciable quantity of reducing substance in the distillate is probably not due to a partial liberation of formaldehyde from the condensation product, as suggested by Bamberger, but to the presence in commercial formaldehyde of unsaturated compounds of unknown character, which apparently, in Bamberger's method (*loc. cit.*), give rise to some extent with the bisulphite and lead to the high results. On account of its cheapness and convenience, the authors admit that Bamberger's method is to be preferred to theirs.—H. B.

Opium: Valuation of ——. [Determination of Morphine in —]. A. and Albert Petit. *J. Pharm. Chim.*, 1905, 1, 107–111.

The committee appointed to investigate current processes for the determination of morphine in opium have recommended the following for adoption as the official method in the forthcoming edition of the French Codex:—

Fifteen grms. of the opium are intimately mixed with 100 grms. of slaked lime; 150 c.c. of distilled water are then added, and, after thorough mixing, left in contact, with occasional stirring, for 2 hours. The mixture is filtered, and 100 c.c. of filtrate, equivalent to 10 grms. of the opium, are collected. To this, 30 c.c. of ether of sp. gr. 0.725 are added, with thorough shaking, so as to separate the aqueous layer; 2 grms. of pure ammonium chloride are then dissolved in the liquid, agitation being continued until a distinct precipitate becomes evident. The whole is then transferred to a precipitating glass, covered with a sheet of glass to prevent undue volatilisation of the ether, and set aside for 24 hours. The ethereal layer is then decanted on to two small counterpoised filters, the remaining aqueous portion being again agitated with another 30 c.c. of ether; this is also decanted on to the filters, followed by the aqueous solution containing the morphine precipitate; when all the morphine has been collected, it is washed with 25 to 30 c.c. of water saturated with morphine, distributed over the precipitate on the filters by means of a fine-pointed pipette. The morphine is then dried in the filters, at 100° C. for 2 hours. The dry filters and their contents are then washed with about 20 c.c. of pure, alcohol-free chloroform, until the chloroform filtrate passes colourless. The morphine is again dried and weighed. The statement of Dott H. Hesse that morphine dried at 100° C. retains 1 mol. of water of crystallisation is confirmed.—J. O. B.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Alkal Hydroxides; Solubility of — in Glycerol. A. Müller. *Z. anorg. Chem.*, 1905, 43, 320–325.

In aqueous solutions of various metallic salts there is added a large proportion of glycerol, and then an excess of ammonia, different effects are observed. Several of

the hydroxides remain in solution, while others are precipitated. The effects vary with the concentration and other conditions; but, under the conditions obtaining in the author's experiment, barium and cerium salts gave an immediate turbidity, whilst aluminium, chromium, ferrous, ferric, cerous and neodymium salts gave clear and variously-coloured liquids. Cerous hydroxide is remarkably soluble under these conditions. If the proportion of salt present is about sufficient to saturate completely the retentivity of the glycerol, then, on dilution with water, the glycerol solution is gradually hydrolysed, and the hydroxide is precipitated, the hydrolysis proceeding more rapidly, the greater the dilution. H. B.

Rhodium and Palladium; Comparative Absorption of Hydrogen by ——. L. Quennessen. *Bull. Soc. Chim.*, 1905, 33, 191–193.

WILM has stated (Ber., 1884, 629) that rhodium has a greater power of absorption for hydrogen than palladium has. This appears to be inaccurate in view of the author's work, in which pure specimens of rhodium ammonium chloride and palladium ammonium chloride were reduced at a dull red heat by means of a current of hydrogen; in each case, when air was admitted to the cooled spongy metal (after replacing the hydrogen atmosphere by one of carbon dioxide), condensation of the oxygen of the air and the hydrogen absorbed by the metal occurred. However, when the metals were heated subsequently at 440° C. *in vacuo*, no evolution of hydrogen from the rhodium was noticed, neither was water formed on admitting air to the metal after cooling; in the case of palladium, abundant formation of water was observed. It thus appears that rhodium behaves more like platinum sponge than like palladium in presence of hydrogen.—T. F. B.

Cane-Sugar; Influence of Metals on the Hydrolysis of ——. R. Vondráček. *Z. physik. Chem.*, 1905, 50, 560.

The author draws attention to the fact that authorities differ as to the effect of metals on the well-known slow inversion of saccharose by boiling water, and proves experimentally that strips of platinum foil do not appreciably influence the rate of inversion; this confirms the results of Lindet (this J., 1904, 330). On the other hand, saccharose is rapidly inverted by boiling water in presence of platinum-black. Sugar solutions acquire a decidedly acid reaction by heating with platinum-black for 15 minutes, and the filtrates undergo inversion on further heating. If, after inverting a sugar solution by treatment with platinum-black for eight hours, the powder be immediately heated with a fresh solution, the latter develops no acidity and is not inverted more rapidly than by water alone; but the inverting property of the platinum-black is restored by exposure to air. Again, platinum-black which has been previously deoxidised by treatment with ammonia has no influence on the rate of inversion by pure water. From these data it is concluded that the inversion by platinum-black is due to the oxygen contained in it, which oxidises a part of the saccharose to one or several organic acids, and thus supplies hydrogen ions to the solution.—W. A. C.

Organo-magnesium Compounds; Action of — on Phthalic Anhydride. H. Bauer. *Ber.*, 1905, 38, 240–241.

The author combined 2 molecules of different organo-magnesium compounds with 4 molecules of phthalic anhydride. Phenylmagnesium bromide formed phthalophenone of m. pt. 115° C. Benzylmagnesium chloride yielded dibenzylphthalide of m. pt. 203–204° C. From *p*-tolylmagnesium bromide a compound of m. pt. 189–190°, but of uncertain constitution, was obtained, but no crystallised body resulted from the action of *p*-bromoanisole and magnesium on phthalic anhydride.—R. L.

New Books.

CHEMISCHE TECHNOLOGIE UND ANALYSE. By Dr. J. L. FETTE AND WACHSE. Von Dr. J. L. FETTE UND WACHSE. In Zwei Bänden. Friedrich Vieweg und Sohn's Verlag, Braunschweig. 1905. Price M.32, Bound M.34.

THIS is the German version of the work referred to in this J., 1904, 802-803. It consists of two volumes, Vol. I, containing 458 pages of subject matter, and Vol. II, 458 pages, and also the alphabetical index, followed by tables of errata for both volumes. The work contains a tabulated sheet, 92 illustrations, and 748 tables. The entire subject is systematised by the following classification: Vol. I. (i) Classification of Oils, Fats and Waxes, with Chemical and Physical Properties; (ii) Saponification of Fats and Waxes; (iii) Their Constituents; (iv) Preparation of Fatty Matters for Examination—Preliminary Tests; (v) Physical Methods for Examining Oils, Fats and Waxes; (vi) Chemical Methods; (vii) Qualitative Methods; (viii) Examination of Fatty Acids; (ix) Oil Unsaponifiable Matters; (x) Detection and Quantitative Determination of Resin; (xi) Application of the foregoing Methods to the systematic Examination of Oils, Fats and Waxes; (xii) Examination by Strictly Scientific Methods. Vol. II. (xiii) Commercial Preparation of Oils, Fats and Waxes; (xiv) Description of the Natural Oils, Fats and Waxes; Methods of Preparing and Examining them and Detecting Adulterations; (xv) Technology of Oils, Fats and Waxes, Technical Investigation of the products of the Oil and Fat Industries; (xvi) Technology of Waste Fats.

THE PRINCIPLES OF CHEMISTRY. By D. MENDELEEFF. Third English Edition. Translated from the Russian (7th edition) by George Kamensky, A.R.S.M., and edited by Thomas H. Pope, B.Sc. Two Volumes. Longmans, Green and Co., 39, Paternoster Row, London; New York and Bombay. 1905. Price 32s. nett.

THIS work is complete in two volumes. Vol. I, contains 639 pages of subject matter with 88 illustrations, and a frontispiece representing Lavoisier. Vol. II, contains 470 pages of subject matter with 22 illustrations, 3 appendices covering 59 pages and alphabetical indexes of Authors and Subjects. The subject matter is systematised and classified as follows:—Vol. I. The Periods of the Chemical Elements. Periodic System of the Elements in Groups and Series. Introduction. (i) Water and its Compounds; (ii) Composition of Water, also Hydrogen; (iii) Oxygen and Saline Combinations; (iv) Ozone and Hydrogen Peroxide, Dalton's Law; (v) Nitrogen and Air; (vi) Compounds of Nitrogen with Hydrogen and Oxygen; (vii) Molecules and Atoms, Gay Lussac and Avogadro's Laws; (viii) Carbon and Hydrocarbons; (ix) Compounds of Carbon with Oxygen and Nitrogen; (x) Sodium Chloride, Berthollet's Laws, Hydrochloric Acid; (xi) The Halogens; (xii) Sodium; (xiii) Potassium, Rubidium, Cesium and Lithium, Spectrum Analysis; (xiv) Valency and Specific Heat of the Metals, Magnesium, Calcium, Strontium, Barium and Beryllium. Vol. II. (xv) Grouping of the Elements, and the Periodic Law; (xvi) Zinc, Cadmium and Mercury; (xvii) Boron, Aluminium, and the Analogous Metals of the Third Group; (xviii) Silicon and the other Elements of the Third Group; (xix) Phosphorus and Other Elements of the Fifth Group; (xx) Sulphur, Selenium and Tellurium; (xxi) Chromium, Molybdenum, Tungsten, Uranium and Manganese; (xxii) Iron, Cobalt and Nickel; (xxiii) Platinum Metals; (xxiv) Copper, Silver and Gold. Appendix I. Attempt to Apply to Chemistry one of the Principles of Newton's Nat. Philosophy. II. Periodic Law of the Chemical Elements. III. Attempt towards a Chemical Conception of the Ether.

CONVERSATIONS ON CHEMISTRY. FIRST STEPS IN CHEMISTRY. By W. OSTWALD. Authorised Translation by E. C. RAMSAY. PART I. GENERAL CHEMISTRY.

John Wiley and Sons, New York; Chapman and H. Ltd., London. 1905. Price 6s. 6d.

SMALL 8vo volume, containing 250 pages of subject matter with 46 illustrations. The author refers, as one of the causes leading him to write this book, arranged on the dialogue principle, "to the feeling of thankfulness with which he even now regards the 'Schule der Chemie' of Stöckhardt," which was the first text-book of Chemistry that was placed in his hands. It is classified as follows: (1) Substances; (2) Properties; (3) Substances and Mixtures; (4) Solutions; (5) Melting and Freezing; Boiling and Evaporation; (7) Measuring; (8) Density; (9) Forms; (10) Combustion; (11) Oxygen; (12) Compounds and Constituents; (13) Elements; (14) and Light and Heavy Metals; (16) More about Oxygen; (17 and 18) Hydrogen, &c.; (19—21) Water, Ice, Steam; (22) Nitrogen; (23) Air; (24) Continuity of Exactness; (25) Expansion of Air by Heat; (26) Water in the Air; (27) Carbon; (28 and 29) Carbon Monoxide and Dioxide; (30) The Sun.

THE MINERAL INDUSTRY DURING 1903. Founded by the late RICHARD P. ROTHWELL. Prepared by the Editorial Staff of the Engineering and Mining Journal. Under the Supervision of D. H. NEWLAND. Vol. 2. The Engineering and Mining Journal, New York and London. 1904.
